NO-MODIFIED HEMOGLOBINS AND USES THEREFOR

RELATED APPLICATIONS

This application is a continuation-in-part of U.S. Patent Application Number 08/796,164 filed on February 6, 1997, which is a continuation-in-part of PCT/US96/14659 filed on September 13, 1996, which is a continuation of U.S. Patent Application Number 08/667,003 filed on June 20, 1996, which is a continuation-in-part of U.S. Patent Application Number 08/616,371 filed on March 15, 1996, which claims priority to U.S. Provisional Application Number 60/003,801 filed on September 15, 1995. This application is also a continuation-in-part of PCT/US96/14660 filed on September 13, 1996, which is a continuation of U.S. Patent Application Number 08/616,259 filed on March 15, 1996, which claims priority to U.S. Provisional Application Number 60/003,801 filed on September 15, 1995. The teachings of all of the above

applications are each incorporated herein by reference in their entirety.

#### GOVERNMENT SUPPORT

This invention was made with government support under  
5 Grant No. NIH RO1 HL52529 awarded by the National  
Institutes of Health. The government has certain rights in  
the invention.

#### BACKGROUND OF THE INVENTION

Interactions of hemoglobin (Hb) with small diffusible  
10 ligands, such as O<sub>2</sub>, CO<sub>2</sub> and NO, are known to occur at its  
metal centers and amino termini. The O<sub>2</sub>/CO<sub>2</sub> delivery  
functions, which arise in the lung and systemic  
microvasculature, are allosterically controlled. Such  
responsiveness to the environment has not been known to  
15 apply in the case of NO. Specifically, it has been thought  
previously that NO does not modify the functional  
properties of Hb to any physiologically significant degree.  
Kinetic modeling predicts that the vast majority of free NO  
in the vasculature should be scavenged by Hb (Lancaster  
20 1994). Accordingly, the steady-state level of NO may fall  
below the K<sub>m</sub> for target enzymes such as guanylate cyclase  
(Lancaster 1994), if not in the unperturbed organism, then  
with oxidant stress such as that found in atherosclerosis.  
These considerations raise the fundamental question of how  
25 NO exerts its biological activity.

One answer to this question is found in the propensity  
of nitric oxide to form S-nitrosothiols (RSNOs) (Gaston, B.  
*et al.*, *Proc. Natl. Acad. Sci. USA* 90:10957-10961 (1993)),  
which retain NO-like vasorelaxant activity (Stamler, J.S.,  
30 *et al.*, *Proc. Natl. Acad. Sci. USA* 89:444-448 (1992)), but  
which can diffuse freely in and out of cells, unlike Hb.

In particular, the NO group of RSNOs possesses nitrosonium (NO<sup>+</sup>) character that distinguishes it from NO itself. It is increasingly appreciated that RSNOs have the capacity to elicit certain functions that NO is incapable of (DeGroote, 5 M.A. et al., *Proc. Natl. Acad. Sci. USA* 92:6399-6403 (1995); Stamler, J.S., *Cell* 78:931-936 (1994)). Moreover, consideration has been given to the possibility that -SNO groups in proteins serve a signaling function, perhaps analogous to phosphorylation (Stamler, J.S. et al., *Proc.* 10 *Natl. Acad. Sci. USA* 89:444-448 (1992); Stamler, J.S. *Cell*, 78:931-926 (1994)). Although S-nitrosylation of proteins can regulate protein function (Stamler, J.S. et al., *Proc. Natl. Acad. Sci. USA* 89:444-448 (1992); Stamler, J.S., *Cell*, 78:931-936 (1994)), intracellular S-nitrosoproteins 15 -- the *sine qua non* of a regulatory posttranslational modification -- has heretofore not been demonstrated.

Hemoglobin is a tetramer composed of two alpha and two beta subunits. In human Hb, each subunit contains one heme, while the beta ( $\beta$ ) subunits also contain highly 20 reactive SH groups (cys $\beta$ 93) (Olson, J.S., *Methods in Enzymology* 76:631-651 (1981); Antonini, E. & Brunori, M. In *Hemoglobin and Myoglobin in Their Reactions with Ligands*, American Elsevier Publishing Co., Inc., New York, pp. 29-31 (1971)). These cysteine residues are highly conserved 25 among species although their function has remained elusive.

NO (nitric oxide) is a biological "messenger molecule" which decreases blood pressure and inhibits platelet function, among other functions. NO freely diffuses from endothelium to vascular smooth muscle and platelet and 30 across neuronal synapses to evoke biological responses. Under some conditions, reactions of NO with other components present in cells and in serum can generate toxic intermediates and products at local concentrations in tissues which are effective at inhibiting the growth of 35 infectious organisms. Thus, it can be seen that a method

of administering an effective concentration of NO or biologically active forms thereof would be beneficial in certain medical disorders.

Platelet activation is an essential component of blood  
5 coagulation and thrombotic diathesis. Activation of  
platelets is also seen in hematologic disorders such as  
sickle cell disease, in which local thrombosis is thought  
to be central to the painful crisis. Inhibition of  
platelet aggregation is therefore an important therapeutic  
10 goal in heart attacks, stroke, peripheral vascular disease  
and shock (disseminated intravascular coagulation).  
Researchers have attempted to give artificial hemoglobins  
to enhance oxygen delivery in all of the above disease  
states. However, as recently pointed out by Olsen and  
15 coworkers, administration of underivatized hemoglobin leads  
to platelet activation at sites of vascular injury (Olsen  
S.B. et al., *Circulation* 93:327-332 (1996)). This major  
problem has led experts to conclude that cell-free  
underivatized hemoglobins pose a significant risk of  
20 causing blood clots in the patient with vascular disease or  
a clotting disorder (Marcus, A.J. and J.B. Broekman,  
*Circulation* 93:208-209 (1996)). New methods of providing  
for an oxygen carrier and/or a method of inhibiting  
platelet activation would be of benefit to patients with  
25 vascular disease or who are otherwise at risk for  
thrombosis.

#### SUMMARY OF THE INVENTION

The invention relates to methods of forming SNO-Hb (S-nitrosohemoglobin, which includes for instance, oxy-,  
30 deoxy-, or met- hemoglobin) by reaction of Hb with S-nitrosothiol in procedures which avoid oxidation of the heme. The invention also includes methods of producing nitrosated (including nitrosylated at thiols or metals) and

nitrated derivatives of hemoglobins in which the heme Fe can be oxidized or not oxidized, depending on the steps of the method. The invention also relates to a method of therapy for a condition in which it is desired to  
5 oxygenate, to scavenge free radicals, or to release NO<sup>+</sup> groups or other forms of biologically active NO to tissues. A composition comprising SNO-Hb in its various forms and combinations thereof (oxy, deoxy, met; specifically S-nitrosylated, or nitrosated or nitrated to various extents)  
10 can be administered to an animal or human in these methods. Compositions comprising thiols and/or NO donating agents can also be administered to enhance the transfer of NO<sup>+</sup> groups. Examples of conditions to be treated by nitrosated or nitrated forms of hemoglobin include ischemic injury,  
15 hypertension, angina, reperfusion injury and inflammation, and diseases characterized by thrombosis. Further embodiments of the invention are methods for assessing oxygen delivery to the tissues of a mammal by measuring SNO-Hb and nitrosylhemoglobin in blood.

20 BRIEF DESCRIPTIONS OF THE DRAWINGS

Figures 1A-1D are spectrographs of different forms of Hb as described in Example 1.

Figure 2A is a graph showing formation, with time, of SNO-Hb by S-nitrosylation.

25 Figure 2B is a graph showing the decomposition, with time, of oxy and deoxy forms of SNO-Hb.

Figure 3A is a graph showing the loading of red blood cells (erythrocytes) with S-nitrosocysteine, over time. The inset is a series of spectrographs of forms of Hb as  
30 described in Example 3.

Figure 3B is a series of tracings recording isometric tone of a rabbit aortic ring following treatment of the aortic ring with various agents as described in Example 3.

Figure 4A is a graph of change in tension of a rabbit aortic ring versus concentration of the Hb used in the experiment.

Figure 4B is a graph of change in tension of a rabbit aortic ring versus concentration of the Hb used in the experiment, where glutathione was also added to test the effect as compared to Figure 4A.

Figure 4C is a graph of the ratio of S-nitrosoglutathione formed/starting SNO-Hb concentration versus time, showing rates of NO group transfer from oxy and met forms of Hb to glutathione.

Figure 4D is a graph of S-nitrosothiols exported from loaded red blood cells over time.

Figure 5 is a graph showing the mean arterial blood pressure in rats after they received various doses of oxyHb ( $\blacktriangle$ ), SNO-oxyHb ( $\blacksquare$ ), or SNO-metHb ( $\bullet$ ).

Figures 6A-6F are a series of tracings recording blood pressure (Figures 6A and 6B), coronary artery diameter (Figures 6C and 6D) and coronary artery flow (Figures 6E and 6F), after administration of S-nitrosohemoglobin to anesthetized dogs.

Figure 7A is a graph illustrating the effect of unmodified HbA<sub>0</sub> on platelet aggregation. The maximal extent of aggregation of platelets is plotted against the concentration of HbA (10 nM to 100  $\mu$ M) preincubated with platelets. Experiments were performed as in Example 9. Vertical bars plotted with each data point indicate the standard deviation.

Figure 7B is a graph illustrating the effect of S-nitroso(oxy)hemoglobin on platelet aggregation. The normalized maximal extent of aggregation of platelets is plotted against the concentration of HbA (10 nM to 100  $\mu$ M) preincubated with platelets.

Figure 7C is a graph illustrating the antiaggregation effects on platelets by S-nitroso(met)hemoglobin.

Figure 8 is a bar graph showing the amount of cGMP (guanosine 3',5'-cyclic phosphoric acid), assayed as in Example 10, for 1, 10 and 100  $\mu$ M concentrations of native Hb, SNO-oxyHb or SNO-metHb interacting with  $10^8$  platelets.

5        Figure 9A is a graph which shows the spectra (absorbance versus wavelength in nanometers) of HbA<sub>0</sub> treated as described in Example 11. The shift in the wavelength of maximum absorbance of spectrum B relative to spectrum A illustrates the extent of addition of NO groups  
10    to HbA<sub>0</sub>.

Figure 9B is a graph which shows the spectra of Hb treated with 100-fold excess S-nitrosoglutathione as described in Example 11.

Figure 9C is a graph which shows the spectra of HbA<sub>0</sub>  
15    treated with excess S-nitrosocysteine as described in Example 11.

Figure 9D is a graph which shows the spectra of rat Hb treated with 100-fold excess S-nitrosocysteine. Spectrum A shows nitrosated Hb not further treated with dithionite;  
20    spectrum B shows nitrosated Hb further treated with dithionite.

Figure 9E is a graph illustrating the increase in nitrosated Hb product with time by reacting HbA<sub>0</sub> with either 100x excess S-nitrosocysteine (top curve) or 10x  
25    excess S-nitrosocysteine (middle curve). HbA<sub>0</sub> was preincubated with 100  $\mu$ M inositol hexaphosphate before reacting with 10x excess S-nitrosocysteine (bottom curve; triangle points). (See Example 11.)

Figure 10 is a graph illustrating the percent change,  
30    with time, in blood flow measured in caudatoputamen nucleus of rats after injection of the rats with: ○, 100 nmol/kg SNO-Hb; ●, 1000 nmol/kg SNO-Hb; or ■, 1000 nmol/kg underivatized Hb (see Example 12).

Figure 11 is a graph illustrating the percent change  
35    in tension of a ring of aorta from rabbit, plotted as a

function of the log of the molar concentration of hemoglobin tested (see Example 13). ●, Hb treated with S-nitrosocysteine at a ratio of 1:1 CYSNO/Hb; ○, Hb treated with CYSNO at a ratio of 10:1 CYSNO/Hb; ♦, Hb treated with CYSNO at a ratio of 100:1.

Figure 12 is a graph of the absorbance versus the wavelength of light (nm), for aqueous solutions of 17  $\mu$ M deoxyhemoglobin, 1  $\mu$ M NO, and varying amounts of dissolved oxygen added by sequential injections of room air. The absorbance of the initial solution (no added air) is shown by the curve with the highest peak at approximately 430 nm. Sequential additions of 50  $\mu$ l of air shift the curve leftwards on the graph. See Example 14.

Figure 13 is a graph showing the yield of SNO-Hb as micromolar concentration (left axis, diamonds) and as % of NO added (right axis, squares), plotted against the heme:NO ratio, when nitrosyl-deoxyHb made at various ratios of heme:NO was exposed to oxygen. See Example 15.

Figure 14A is a graph showing difference spectra (each a spectrum of the NO and Hb mixture minus spectrum of the starting deoxyHb), for 17  $\mu$ M hemoglobin and NO mixtures, for the concentrations of NO shown. See Example 16.

Figure 14B is a graph showing the peak wavelength of the difference spectra plotted against the concentration of nitric oxide added to the solution as in Figure 14B.

Figure 15A is a graph showing difference spectra (deoxyhemoglobin and air mixtures minus initial deoxyhemoglobin spectrum), for successive additions of air.

Figure 15B is a graph showing difference spectra (20  $\mu$ M deoxyhemoglobin and 1  $\mu$ M NO mixture, with successive additions of air, minus initial deoxyhemoglobin spectrum). See Example 17.

Figure 16 is a graph showing two difference spectra ( $A_{418}$  of hemoglobin and NO solution at heme:NO 20:1 minus

initial deoxyhemoglobin A<sub>418</sub>) for the mutant  $\beta$ 93Ala Hb and wild type  $\beta$ 93Cys Hb. See Example 18.

Figure 17 is a graph showing the yield of SNO-Hb as micromolar concentration (left axis, diamonds) and as % of NO added (right axis, squares), plotted against the heme:NO ratio, when nitrosyl-deoxyHb made at various ratios of heme:NO was exposed to oxygen. See Example 19.

Figure 18A is a graph showing the percentage content of oxidized hemoglobin (metHb) for different concentrations of Hb (symbols below) to which NO was added to reach varying final concentrations (horizontal axis).

◆ represents 1.26  $\mu$ M hemoglobin, ■ represents 5.6  $\mu$ M hemoglobin, ▲ represents 7.0  $\mu$ M hemoglobin, X represents 10.3  $\mu$ M hemoglobin, \* represents 13.3  $\mu$ M hemoglobin, and ● represents 18.3  $\mu$ M hemoglobin. See Example 20.

Figure 18B is a graph showing the yield of oxidized hemoglobin ( $\mu$ M) plotted against the final concentration of NO added to solutions of Hb at the concentrations indicated by the symbols as for Figure 18A.

Figure 19 is a graph showing the concentration of oxidized Hb (metHb) plotted against the NO concentration, in experiments performed as described in Example 21 in 10 mM (◆), 100 mM (Δ), or 1 M (\*) sodium phosphate buffer, pH 7.4.

Figures 20A and 20B are graphs showing the contractile effects of oxyHb, SNO-oxyHb, deoxy-Hb and SNO-deoxy-Hb on thoracic aortic ring isolated from rabbit. Measurements are percent increase in tension of aortic ring as a function of the log of the concentration of hemoglobin or SNO-hemoglobin. Measurements are made after the tension has stabilized.

Figure 20C is a graph showing the percent change in tension of contracted aortic ring as a function of the log concentration of SNO-hemoglobin at the concentrations of O<sub>2</sub> indicated, in addition to 10  $\mu$ M glutathione.

Figure 20D is a graph showing the percent change in tension of contracted aortic ring as a function of the log concentration of SNO-glutathione, in the concentrations of O<sub>2</sub> indicated.

5        Figure 21A and Figure 21B are each a series of four graphs illustrating the change with time in tension of rabbit aortic ring upon the addition of red blood cells treated with S-nitrosocysteine ("red blood cells loaded with nitric oxide"), or untreated red blood cells, as  
10 indicated, in the concentration of O<sub>2</sub> indicated. Figure 21C is a graph illustrating the change with time in tension of rabbit aortic ring contracted with phenylephrine under hypoxic conditions (6-7 torr) and then exposed to either 1 μM Hb or SNO-Hb.

15        Figure 22 is a bar graph depicting the concentrations of FeNO/Hb and SNO/Hb in venous or arterial blood as measured in Example 24. ATA=atmospheres of absolute pressure.

20        Figures 23A-23I are each a graph showing the effects of SNO-Hb (●) and Hb (■) (1 μmol/kg infused over 3 minutes) on local blood flow in substantia nigra (SN), caudate putamen nucleus, and parietal cortex of rats, in 21% O<sub>2</sub> (Figures 23A, 23B and 23C), in 100% O<sub>2</sub> (Figures 23D, 23E and 23F), and in 100% O<sub>2</sub> at 3 atmospheres absolute pressure  
25 (Figures 23G, 23H and 23I) as measured in Example 25.

Figure 24A is a bar graph showing the percent change in blood pressure of rats, during exposure to three different conditions (inspired O<sub>2</sub> concentrations of 21%, 100%, or 100% O<sub>2</sub> at 3 ATA) upon infusion of GSNO, SNO-Hb,  
30 or Hb, as tested in Example 26.

Figure 24B is a bar graph showing the percent change in blood pressure of rats [pre-administered (+ L-NMMA), or not preadministered (- L-NMMA), N<sup>G</sup>-monomethyl-L-arginine] upon infusion of SNO-RBCs, as tested in Example 26.

## DETAILED DESCRIPTION OF THE INVENTION

### Roles for Hemoglobin in Physiology

The increase in SNO-Hb content of red cells across the pulmonary circuit (right ventricular inport-left ventricle) suggests that the Hb molecule is S-nitrosylated in the lung. Selective transfer of the NO group from endogenous RSNOs found in lung (Gaston, et al. (1993)) and blood (Scharfstein, J.S. et al., *J. Clin. Invest.* 94:1432-1439 (1995)) to SH groups of Hb, substantiate these findings. The corresponding decline in Hb(FeII)NO levels across the pulmonary bed reveals a role for the lung either in the elimination of NO or in its intramolecular transfer from heme to cys $\beta$ 93. Taken in aggregate, these data extend the list of function-regulating interactions of Hb with small molecules within the respiratory system, previously known to include the elimination of CO and CO<sub>2</sub>, and uptake of O<sub>2</sub>. Since, as demonstrated herein, oxygenation of Hb leads to structural changes that increase the NO-related reactivity of cys $\beta$ 93, O<sub>2</sub> can now be regarded as an allosteric effector of Hb S-nitrosylation.

The arterial-venous difference in SNO-Hb concentration suggests that the protein acts as an NO group donor in the systemic circulation. There is good indication that SNO-Hb functions in regulation of vasomotor tone. In the microcirculation, where control of blood pressure is achieved, erythrocytes come in intimate contact with endothelial surfaces. Under these conditions, Hb can contract the vasculature by sharply decreasing the steady state level of free NO (Lancaster, J.R., (1994)). This is believed to contribute to the increases in blood pressure that occur with infusion of cell-free Hbs (Vogel, W.M., et al., *Am. J. Physiol.*, 251:H413-H420 (1986); Olsen, S.B., et al., *Circulation* 93:329-332 (1996)). The transient nature of such hypertensive responses, however, is consistent with

the subsequent formation of SNO-Hb which counteracts this effect, evidenced by its lowering of blood pressure at naturally occurring concentrations. Thus, the capacity of the erythrocyte to support the synthesis and metabolism of SNO-Hb is important for normal blood flow.

Mammals must have adopted unique molecular mechanisms to ensure adequate NO delivery in the microcirculation. Results herein suggest that Hb has evolved both electronic and conformational switching mechanisms to achieve NO homeostasis. Specifically, NO scavenging by the metal center(s) of SNO-Hb(FeII)O<sub>2</sub> is sensed through its conversion to met(FeIII) (Figure 1B). This electronic switch effects decomposition of SNO-Hb with NO group release (Figures 3A, 3B, 4A). In this manner, the NO-related activity of SNO-Hb is partly determined by the amount of NO scavenged. Changes in O<sub>2</sub> tension also function to regulate NO delivery, as it is observed herein that NO release is facilitated by deoxygenation. This allosteric effect promotes the efficient utilization of O<sub>2</sub>, as NO controls mitochondrial respiration (Shen, W., et al., *Circulation* 92:3505-3512 (1995)).

S-nitrosothiol groups in proteins have been implicated in NO metabolism and in regulation of cellular functions (Stamler, J.S., et al., *Proc. Natl. Acad. Sci. USA* 89:444-448 (1992); Stamler, J.S., *Cell* 78:931-936 (1994)). The identification of SNO-Hb in erythrocytes is the first demonstration of an intracellular S-nitrosoprotein and gives further credence to the role of such proteins in cellular regulation. The question arises as to how SNO-Hb relaxes blood vessels when any free NO released would be scavenged instantaneously by Hb itself according to previous theories (Lancaster, J.R., (1994)). Noteworthy in this regard are studies showing that RSNO activity involves nitrosyl (NO<sup>+</sup>) transfer to thiol acceptors (Scharfstein, J.S., et al., (1994); Arnelle, D.R. and Stamler, J.S.,

Arch. Biochem. Biophys. 318:279-285 (1995); Stamler, J.S.,  
et al., Proc. Natl. Acad. Sci. USA 89:7674-7677 (1992)),  
which serve to protect the NO-related activity from  
inactivation at metal centers. Findings presented herein  
5 indicate that S-nitrosothiol/thiol exchange with  
glutathione (forming GSNO) occurs within erythrocytes, and  
is influenced by the oxidation state of heme and its  
occupation by ligand. Certain activities of GSNO in  
bacteria require transport of intact dipeptide (i.e., S-  
10 nitrosocysteinylglycine) across the cell membrane  
(DeGroote, M.A., et al., Proc. Natl. Acad. Sci. USA  
92:6399-6403 (1995)). The data presented below in the  
Examples show that S-nitrosothiol transport occurs also in  
eukaryotic cells. GSNO, or related thiol carriers exported  
15 by erythrocytes (Kondo, T., et al., Methods in Enzymology,  
Packer, L., ed., Academic Press, 252:72-83 (1995)), might  
also initiate signaling in or at the plasmalemma (Stamler,  
J.S., Cell 78:931-936 (1994)), given reports of thiol-  
dependent activation of potassium channels by EDRF  
20 (Bolotina, V.M., et al., Nature 368:850-853 (1994)).  
Alternative possibilities also merit consideration. In  
particular, reports that Hb associates with red cell  
membranes via cys $\beta$ 93 (Salhany, J.M. and Gaines, K.C.,  
Trends in Biochem. Sci., pp. 13-15 (Jan. 1981)) places Hb  
25 in a position to donate the NO group directly to contacting  
endothelial surfaces, perhaps via SNO/SH exchange. Cell  
surface interactions appear to be operative in signaling  
mediated by other S-nitrosoproteins (Stamler, J.S., et al.,  
Proc. Natl. Acad. Sci. USA, 89:444-448 (1992); Stamler,  
30 J.S., Cell, 78:931-936 (1994)).

The highly conserved Cys $\beta$ 93 residues in Hb influence  
the oxygen affinity and redox potential of the heme iron  
and its physiochemical properties (Garel, C., et al.,  
Biochem. 123:513-519 (1982); Jocelyn, P.C., et al.,  
35 Biochemistry of the SH Group, p. 243, Academic Press,

London; (1972); Craescu, C.T., *J. Biol. Chem.* 261:14710-14716 (1986); Mansouri, A., *Biochem. Biophys. Res. Commun.*, 89:441-447 (1979)). Nonetheless, their long sought-after physiological function has remained a mystery. The studies  
5 herein suggest new sensory and regulatory roles for Hb, in which Cys $\beta$ 93 functions in transducing NO-related signals to the vessel wall. In particular, the physiological function of Cys $\beta$ 93, which is invariant in all mammals and birds, is to deliver under allosteric control, NO-related biological  
10 activity that cannot be scavenged by heme. Thus, these data bring to light a dynamic circuit for the NO group in which intraerythrocytic Hb participates as both a sink and a donor, depending on its microenvironment. Such observations provide answers to paradoxes that arise from  
15 conceptual frameworks based solely on diffusional spread and reaction of free NO (Lancaster, J.R., (1994); Wood and Garthwaite, *J. Neuropharmacology* 33:1235-1244 (1994)); and has implications that extend to other thiol- and metal-containing (heme) proteins, such as nitric oxide synthase  
20 and guanylate cyclase.

The discoveries reported here have direct therapeutic implications. Specifically, concerns over loss of NO-related activity due to inactivation by blood Hb (Lancaster, J.R., (1994)) are obviated by the presence of  
25 an RSNO subject to allosteric control. SNO-Hb is free of the adverse hypertensive properties of cell-free Hb preparations that result from NO scavenging at the metal centers. A composition comprising one or more of the various forms of cell-free SNO-Hb (e.g., SNO-Hb[FeII]O<sub>2</sub>,  
30 SNO-Hb[FeIII], SNO-Hb[FeII]CO) can be administered in a pharmaceutically acceptable vehicle to a human or other mammal to act as a blood substitute.

Blood Flow Regulation by S-Nitrosohemoglobin is Controlled  
by the Physiological Oxygen Gradient

In the classical allosteric model, Hb exists in two alternative structures, named R (for relaxed, high O<sub>2</sub> affinity) and T (for tense, low O<sub>2</sub> affinity). The rapid transit time of blood through the capillaries requires that Hb assume the T-structure to efficiently deliver O<sub>2</sub> (M.F. Perutz, pp. 127-178 in *Molecular Basis of Blood Diseases*, G. Stamatayanopoulos, Ed. (W.B. Saunders Co., Philadelphia, 1987); Voet, D. and Voet, J.G., pp. 215-235 (John Wiley & Sons Inc., New York, 1995). The switch from R to T in RBCs normally takes place when the second molecule of O<sub>2</sub> is liberated. This allosteric transition also controls the reactivity of two highly conserved cysteine $\beta$ 93 residues that can react with 'NO'. Thiol affinity for NO is high in the R-structure and low in T. This means that the NO group is released from thiols of Hb in low PO<sub>2</sub> and explains the arterial-venous (A-V) difference in the S-nitrosohemoglobin (SNO-Hb) level of blood (see Table 2, Example 8). A major function of (S)NO in the vasculature is to regulate blood flow, which is controlled by the resistance arterioles (Guyton, A.C., in *Textbook of Medical Physiology* (W.B. Saunders Co., Philadelphia, 1981) pp. 504-513). It is shown from the Examples herein that (partial) deoxygenation of SNO-Hb in these vessels (Duling, B. and Berne, R.M. *Circulation Research*, 27:669 (1970); Popel, A.S., et al., (erratum *Am. J. Physiol.* 26(3) pt. 2). *Am. J. Physiol.* 256, H921 (1989); Swain, D.P. and Pittman, R.N. *Am. J. Physiol.* 256, H247-H255 (1989); Torres, I. et al., *Microvasc. Res.*, 51:202-212 (1996); Buerk, D. et al., *Microvasc. Res.*, 45:134-148 (1993)) actually promotes O<sub>2</sub> delivery by liberating (S)NO. That is, the allosteric transition in Hb functions to release (S)NO in order to increase blood flow.

O<sub>2</sub> delivery to tissues is a function of the O<sub>2</sub> content of blood and blood flow (Dewhirst, M.W. *et al.*, *Cancer Res.*, 54:3333-3336 (1994); Kerger, H. *et al.*, *Am. J. Physiol.*, 268:H802-H810 (1995)). Blood oxygen content is largely determined by Hb, which undergoes allosteric transitions in the lung and systemic microvasculature that promote the binding and release of O<sub>2</sub> (L. Stryer, in *Biochemistry* L. Stryer, Ed. (W.H. Freeman & Co., San Francisco, 1981) pp. 43-82; Guyton, A.C. in *Textbook of Medical Physiology* (W.B. Saunders Co., Philadelphia, 1981); Perutz, M.F., pp. 127-178 in *Molecular Basis of Blood Diseases*, G. Stamatayanopoulos, Ed. (W.B. Saunders Co., Philadelphia, 1987); Voet, D. and Voet, J.G. (John Wiley & Sons Inc., New York, 1995) pp. 215-235 pp. 208-215, 224-225, 230-245, 344-355)). Intimate contact between erythrocyte and endothelium is believed to facilitate O<sub>2</sub> delivery by minimizing the distance for O<sub>2</sub> diffusion into surrounding tissues (Caro, C.G. *et al.*, Oxford University Press, Oxford, 363 (1978)). On the other hand, regional blood flow is regulated by metabolic requirements of the tissue: blood flow is increased by hypoxia and decreased when O<sub>2</sub> supply exceeds demand (Guyton, A.C., in *Textbook of Medical Physiology* (W.B. Saunders Co., Philadelphia, 1981) pp. 504-513)). These classical physiological responses are thought to be partly mediated by changes in the level of endothelial-derived NO and its biological equivalents (Park, K.H. *et al.*, *Circ. Res.*, 71:992-1001 (1992); Hampl, V. *et al.*, *J. Appl. Physiol.* 75(4):1748-1757 (1993)).

This standard picture has its problems. First, it is puzzling that significant O<sub>2</sub> exchange occurs in the precapillary resistance vessels (evidenced by the periarteriolar O<sub>2</sub> gradient; Duling, B. and Berne, R.M. *Circulation Research*, 27:669 (1970); Popel, A.S., *et al.*, (erratum *Am. J. Physiol.* 26(3) pt. 2). *Am. J. Physiol.* 256, H921 (1989); Swain, D.P. and Pittman, R.N. *Am. J.*

Physiol. 256, H247-H255 (1989); Torres, I. et al.,  
Microvasc. Res., 51:202-212 (1996); Buerk, D. et al.,  
Microvasc. Res., 45:134-148 (1993)). Why is O<sub>2</sub> lost to  
counter-current venous exchange prior to reaching the  
5 tissues? Second, close contact between endothelial  
surfaces and erythrocytes leads to sequestration of NO by  
Hb (Stamler, J.S., Nature, 380:108-111 (1996); Perutz,  
M.F., Nature, 380:205-206 (1996)). Decreases in the  
steady-state levels of NO in terminal arterioles (King,  
10 C.E. et al., J. Appl. Physiol., 76(3):1166-1171 (1994);  
Shen, W. et al., Circulation, 92:3505-3512 (1995); Kobzik,  
L. et al., Biochem. Biophys. Res. Comm., 211(2):375-381  
(1995); Persson, M.G., et al., Br. J. Pharmacol., 100:463-  
466 (1990) and capillaries (Mitchell, D., and Tyml, K., Am.  
15 J. Physiol., 270 Heart Circ. Physiol., 39), H1696-H1703  
(1996)) contract blood vessels, blunt hypoxic vasodilation  
and reduce red cell velocity. This line of reasoning leads  
to the paradox: the red blood cell seems to oppose its own  
O<sub>2</sub> delivery function (note in vivo effects of Hb in Figures  
20 10A-10I).

The finding that the O<sub>2</sub> gradient in precapillary  
resistance vessels promotes NO group release from SNO-Hb  
appears to solve these problems. SNO-Hb compensates for NO  
scavenging at the heme iron by assuming the T-structure  
25 which liberates SNO. Specifically, Cys93 donates the NO  
group in deoxy structure whereas it cannot do so in the oxy  
conformation. Accordingly, the O<sub>2</sub> gradient determines  
whether SNO-Hb dilates or constricts blood vessels. Stated  
another way, SNO-Hb senses the tissue PO<sub>2</sub> (i.e., the  
30 periarteriolar O<sub>2</sub> gradient) and then utilizes the  
allosteric transition as a means to control arteriolar  
tone. If the tissue is hypoxic (i.e., the O<sub>2</sub> gradient is  
high), SNO is released to improve blood flow. However, if  
O<sub>2</sub> supply exceeds demand (i.e., the O<sub>2</sub> gradient is small),  
35 SNO-Hb holds on to the NO group by maintaining the R-

structure--with the net effect of reducing blood flow in line with demand. SNO-Hb thereby contributes to the classical physiological responses of hypoxic vasodilation and hyperoxic vasoconstriction.

5       Based on studies described herein, especially Examples 22-26, the following picture emerges. Partially nitrosylated Hb ( $\text{Hb[FeII]NO}$ ) enters the lung in T-structure (see venous measurements in Figure 22). There, S-nitrosylation is facilitated by the  $\text{O}_2$ -induced  
10 conformational change in Hb. SNO-oxyHb ( $\text{SNO-Hb[FeII]O}_2$ ) enters the systemic circulation in R-structure (see arterial levels in Figure 22). Oxygen losses in precapillary resistance vessels then effect an allosteric transition (from R to T) in Hb which liberates 'NO' to  
15 dilate blood vessels (see especially Figures 20D and 23A-C). NO released from Hb is transferred directly to the endothelium, or by way of low mass S-nitrosothiols--such as GSNO--which are exported from RBCs (see Figure 4D and Example 4; see also Figures 20C and 24A). Thus, the  $\text{O}_2$   
20 gradient in arterioles serves to enhance  $\text{O}_2$  delivery: it promotes an allosteric transition in Hb which releases NO-related activity to improve blood flow.

#### Assay methods

25       The invention also relates to a method for determining the concentration of nitrosyl(FeII)- hemoglobin in a blood sample, thereby serving as a measure of the level of NO in the animal or human from which the blood sample has been taken. The method is related to one used previously for the measurement of S-nitroso proteins and smaller molecular  
30 weight S-nitrosothiols in plasma (See U.S. Patent No. 5,459,076; Oct. 17, 1995. The contents of this patent are hereby incorporated by reference in their entirety.) However, the primary focus of the present invention is on

assaying for nitrosyl(FeII)-hemoglobin rather than S-nitrosothiols.

In contrast to the previous method, in which the red blood cells were removed and discarded from the sample to be analyzed, the subject invention method uses the red blood cells. The method measures NO which has reacted with the thiol groups of hemoglobin in the form of S-nitroso-hemoglobin (SNO-Hb) as well as NO bound to the Fe of the heme (nitrosyl(FeII)-hemoglobin or Hb(FeII)NO). As shown in the table, the level of S-nitroso-hemoglobin in venous blood is negligible compared to the level of Hb(FeII)NO. Therefore, to specifically measure the level of Hb(FeII)NO in venous blood, it is unnecessary to include steps in which Hb samples are divided into two aliquots which are then either treated or not treated with a 10-fold excess of HgCl<sub>2</sub> over the protein concentration. Reaction of Hb with HgCl<sub>2</sub> removes NO from thiol groups selectively, without disturbing NO bound at the heme. Values for NO obtained from the HgCl<sub>2</sub> reaction, if significant, should be subtracted from the total NO obtained for the measurements without the HgCl<sub>2</sub> reaction, to obtain an accurate value for Hb(FeII)NO.

In one embodiment of the invention, a blood sample is taken from a mammal, such as a human, and the solid parts including cells are isolated away from the remaining fluid. The cells are then lysed by standard methods, and a protein fraction is prepared. Before quantitating nitric oxide adducts (nitrosonium adducts, which include low molecular weight S-nitrosothiols such as S-nitrosoglutathione and high molecular weight S-nitrosothiols such as S-nitroso-proteins), it is preferable to first remove low molecular weight S-nitrosothiols endogenous to the red blood cells, which would also contribute to the NO value, by a step which separates low molecular weight molecules away from the red blood cell proteins (referred to as desalting).

This step can include, for example, dialysis or column chromatography based on separation by size of the molecules. A further step is to subject the protein fraction to photolysis, as in a photolysis cell, where it  
5 is irradiated with light of the appropriate wavelength to liberate NO from the various forms of hemoglobin. The resulting NO is detected by reaction with ozone.

One embodiment of the invention utilizes a chemiluminescence apparatus in which a photolysis cell is  
10 linked directly to the reaction chamber and detector portion, thereby bypassing the pyrolyzer. A sample of the blood protein fraction is injected into the photolysis cell, either directly, or as chromatographic effluent from a high-performance liquid or gas chromatography system  
15 which is connected to the photolysis cell.

The sample is then irradiated with a mercury vapor lamp, and directed through a series of cold traps, where liquid and gaseous fractions which are less volatile than nitric oxide (such as nitrite and nitrate) are eliminated,  
20 leaving only free nitric oxide remaining in the cell. The nitric oxide is then transported by a gaseous stream, preferably helium, into the chemiluminescence spectrometer. In the alternative, other inert gases may be used.

Once present in the chemiluminescence spectrometer,  
25 the free nitric oxide is detected by its chemical reaction with ozone, resulting in the generation of signals that are recorded on a digital integrator. If desired, flow rates and illumination levels in the photolysis cell can be adjusted to cause complete photolysis of the S-nitric oxide  
30 bond of the S-nitrosothiol compounds. Flow rates and illumination levels may be adjusted by routine methods available in the art, in order to achieve optimal cleavage of the bond between the particular adduct and nitric oxide, nitrosonium or nitroxyl, whichever is bound.

In a variation, the invention relates to a method for detecting S-nitrosothiols, including primarily S-nitroso-hemoglobin (SNO-Hb) in a blood sample. This method comprises inactivating the chemiluminescence, signal-  
5 generating capability of any nitric oxide which is associated with a thiol, in the protein fraction derived from the blood sample, and determining the amount of thiol-bound nitric oxide by measuring the quantitative difference between total nitric oxide and nitric oxide remaining after  
10 inactivation.

A particular embodiment of this variation relates to a method in which the protein fraction derived from the blood sample is treated with a source of mercury ions, mercuric ions being preferred, followed by air incubation, which  
15 oxidizes the nitric oxide and nitrosonium and renders them undetectable. Compounds suitable for pretreatment include  $\text{Hg}_2\text{Cl}_2$  and other mercurous ion salts and organic mercurials. The treated sample is then injected into the photolysis cell, where  $\text{NO}^+$  is converted to  $\text{NO}^\bullet$  (nitric  
20 oxide) and the nitric oxide is detected by the chemiluminescence method described above. The amount of nitric oxide which is specifically derived from S-nitrosothiols is determined by comparing the chemiluminescence signal generated by the mercury ion-  
25 treated sample, with a chemiluminescence signal generated by a sample of the equivalent biological fluid which is not treated with mercury ion prior to injection into the photolysis cell.

In a further embodiment of the claimed invention, the  
30 methods described herein can be utilized to determine the presence of a disease state which involves abnormal levels of nitric oxide and its biologically active equivalents, by monitoring  $\text{Hb(FeII)NO}$  and SNO-Hb levels in blood, and more particularly,  $\text{Hb(FeII)NO}$  in venous blood from a patient.  
35 The ability to specifically assay for  $\text{Hb(FeII)NO}$  in venous

blood distinguishes this assay over previously known methods. Nitric oxide adducts represent a pool of bioactive nitric oxide in physiological systems. Therefore, in disease states in which the pathogenesis  
5 derives from the effects of abnormal levels of nitric oxide, these methods provide a means for the clinician to determine the presence of, and monitor the extent of, the disease state. Such information enables the clinician to determine the appropriate pharmacological intervention  
10 necessary to treat the disease state. Such disease states and medical disorders include, but are not limited to, respiratory distress, septic shock, cardiogenic shock, hypovolemic shock, atherosclerosis, hyperhomocysteinemia, venous thrombosis, arterial thrombosis, coronary occlusion,  
15 pulmonary embolism, cerebrovascular accidents, vascular fibrosis, ectopia lentis, osteoporosis, mental retardation, skeletal deformities, pulmonary hypertension, malignancy, infections, inflammation, asthma, tolerance to narcotics and central nervous system disorders. Furthermore, the use  
20 of these methods is not limited to these diseases. This method can be of use in assaying biologically active nitric oxide equivalents in any disease state or medical disorder in which nitric oxide is implicated.

The data set forth in the Examples below demonstrate  
25 that a determination of NO bound to hemoglobin as nitrosylhemoglobin and SNO-Hb can be used to assess the efficiency of oxygen delivery to the tissues of an animal or a human patient. Values for nitrosylhemoglobin and SNO-Hb in blood can be determined together, in one method, or  
30 they can be determined in separate methods. An additional determination for oxygen in the blood, as measured by methods known in the art, can be used in conjunction with determinations of nitrosylhemoglobin and SNO-Hb concentrations, to assess oxygen delivery to a site in the  
35 body from which a blood sample is taken.

Further embodiments

The subject invention relates to a method of loading cells with a nitrosating agent as exemplified for red blood cells as in Figure 3A, but which can be accomplished in  
5 more ways. Suitable conditions for pH and for the temperature of incubation are, for example, a range of pH 7-9, with pH 8 being preferred, and a temperature range of 25 to 37°C. For red blood cells, short incubation times of 1 to 3 minutes are preferred for limiting the formation of  
10 S-nitrosylated forms of Hb. However, intracellular concentrations of 1 mM nitrosating agent can be reached.

The nitrosating agent should be a good donor of NO<sup>+</sup> and should be able to diffuse through the cell membrane of the target cell type. That is, it is preferably of low  
15 molecular weight, compared to the molecular weight of S-nitroso proteins. Examples are S-nitroso-N-acetylcysteine, S-nitrosocysteinyglycine, S-nitrosocysteine, S-nitrosohomocysteine, organic nitrates and nitrites, metal nitrosyl complexes, S-nitro and S-nitroso compounds,  
20 thionitrites, diazeniumdiolates, and other related nitrosating agents as defined in Feelisch, M. and Stamler, J.S., "Donors of Nitrogen Oxides" chapter 7, pp. 71-115 *In Methods in Nitric Oxide Research* (Feelisch, M. and Stamler, J.S., eds.) John Wiley and Sons, Ltd., Chichester,  
25 U.K. (1996), the contents of which chapter are hereby incorporated by reference in their entirety. Nitrosating agents have differential activities for different reactive groups on metal-containing proteins. A nitrosating agent can be chosen for minimal oxidation of the heme iron of Hb,  
30 and maximum activity in nitrosylating thiol groups such as found on cysteine. Assay methods are available for detection of nitrosation products, including S-nitrosothiols. See Stamler et al., U.S. Patent Number 5,459,076, the contents of which are hereby incorporated by  
35 reference in their entirety. See also, for example,

- Keefer, L.K., and Williams, D. L. H., "Detection of Nitric Oxide Via its Derived Nitrosation Products," chapter 35, pp. 509-519 *In Methods in Nitric Oxide Research* (Freelisch, M. and Stamler, J.S., eds.) John Wiley and Sons, Ltd., Chichester, U.K., 1996; see also Stamler, J.S. and Feelisch, M., "Preparation and Detection of S-Nitrosothiols," chapter 36, pp. 521-539, *ibid.* Nitrite and nitrate products can be assayed by methods described, for instance, in Schmidt, H.H.H.W. and Kelm, M., "Determination of Nitrite and Nitrate by the Griess Reaction," chapter 33, pp. 491-497, *ibid.*, and in Leone, A.M. and Kelm, M., "Capillary Electrophoretic and Liquid Chromatographic Analysis of Nitrite and Nitrate," chapter 34, pp. 499-507, *ibid.*
- 15        Such low molecular weight nitrosating agents can be used in red blood cells to deliver NO-related activity to tissues. Treatment of red blood cells with nitrosating agent further serves to increase the O<sub>2</sub> delivery capacity of red blood cells. Such treatment of red blood cells also
- 20 allows for the scavenging of free radicals, such as oxygen free radicals, throughout the circulation. It is possible to load red blood cells with S-nitrosothiol, for example, by a process of removing whole blood from a patient's body (as a minimal method of isolating red blood cells),
- 25 treating the red blood cells with low molecular weight nitrosating agent, such as by incubating the red blood cells in a solution of S-nitrosothiol, and then reintroducing the red blood cells into the same patient, thereby allowing the treatment of a number of types of
- 30 diseases and medical disorders, such as those which are characterized by abnormal O<sub>2</sub> metabolism of tissues, oxygen-related toxicity, abnormal vascular tone, abnormal red blood cell adhesion, and/or abnormal O<sub>2</sub> delivery by red blood cells. Such diseases can include, but are not
- 35 limited to, ischemic injury, hypertension, shock, angina,

stroke, reperfusion injury, acute lung injury, sickle cell anemia, and blood borne infectious diseases such as schistosomiasis and malaria. The use of such "loaded" red blood cells also extends to blood substitute therapy and to the preservation of living organs, such as organs for transplantation. In some cases, it will be appropriate to treat a patient with loaded red blood cells originating from a different person.

A particular illustration of the mechanism of the treatment method is presented here by considering sickle cell anemia. Sickle cell patients suffer from frequent vascular occlusive crises which manifest in clinical syndromes such as the acute chest syndrome and hepatic dysfunction. Both endothelial cell dysfunction, resulting in a clotting diathesis as well as dysfunction intrinsic to the red blood cell, are central to disease pathogenesis. At the molecular level, the increased expression of vascular adhesion molecules such as VCAM promote the adhesion of sickled red blood cells containing abnormal hemoglobin. It follows that decreasing cytokine expression on endothelial cells, promoting endothelial function and attenuating red cell sickling, are key therapeutic objectives. However, currently used therapies have been generally unsuccessful.

In this novel method for loading red blood cells with intracellular NO-donor S-nitrosothiols, the effect is to increase oxygen affinity -- which in and of itself should attenuate red blood cell sickling -- and to endow the red blood cell with vasodilator and antiplatelet activity, which should reverse the vasoocclusive crisis. Moreover, nitric oxide should attenuate the expression of adhesion molecules on endothelial cell surfaces, thus restoring endothelial function.

Herein is described a novel therapeutic approach to the treatment of sickle cell disease which involves loading

of red blood cells with S-nitrosothiols or other nitrosating agents. Two examples of therapeutic approaches are given. In the first, the patient's own red blood cells are S-nitrosated extracorporeally (yielding "loaded" red  
5 blood cells) and then given to the patient. The second approach is to directly administer to a patient an agent such as S-nitrosocysteine, which is permeable to red blood cells.

For some diseases or disorders, the administration of  
10 NO-loaded red blood cells is especially desirable. Upon a change from the oxygenated to the deoxygenated state, or upon a change in the oxidation state of the heme Fe from the reduced state (FeII) to the oxidized (FeIII) state, NO is released from the thiol groups of hemoglobin, and is  
15 rapidly transferred to glutathione to form S-nitrosoglutathione. Red blood cells are known to have a high concentration of glutathione. S-nitrosoglutathione efficiently delivers NO to tissues.

In another aspect, the invention is a method for the  
20 treatment of infection by administering to an infected mammal an agent which causes S-nitrosation of thiol groups within the cells which are the target of such agent. For example, an S-nitrosothiol to which lymphocytes are highly permeable can be administered to a patient infected with  
25 HIV. Such treatment for HIV can also be used extracorporeally, to blood isolated from the patient. In another application, the infection is bacterial, and the S-nitrosothiol to be used as an anti-bacterial agent is one to which the target bacterial cells are highly permeable,  
30 as compared to the permeability properties of the host cells. (See, for example De Groote, M.A., et al., *Proc. Natl. Acad. Sci. USA* 92:6399-6403 (1995).) Alternatively, nitrosothiols can be used to treat *Plasmodium falciparum* within red blood cells.

Another embodiment of the invention is a method for specifically modifying a protein containing one or more metal atoms so that the protein becomes S-nitrosylated at one or more thiol groups without modifying the metal, as by  
5 changing the oxidation state or causing the metal atoms to bind NO. This can be accomplished by the use of a reagent which possesses NO<sup>+</sup> character, such as a nitrosothiol (See, for instance, Example 4A.), which reacts specifically with thiol groups of a protein in which metal is bound.

10 An S-nitrosation method has been devised which does not affect the heme of hemoglobin. SNO-Hb (SNO-Hb(FeII)O<sub>2</sub>) can be synthesized from Hb(FeII)O<sub>2</sub> with up to 2 SNO groups per tetramer without oxidation of the heme Fe from FeII to FeIII. In contrast, when Hb(FeII)O<sub>2</sub> is incubated with  
15 excess nitric oxide or nitrite, methemoglobin (HbFe[III]) forms rapidly (Example 1B) and to a significant extent. When Hb[FeII] is incubated with nitric oxide, NO binds rapidly to the heme, forming Hb(FeII)NO to a significant extent (Example 1A).

20 Although rates of formation of SNO-Hb(FeII)O<sub>2</sub> from Hb(FeII)O<sub>2</sub> are more rapid (see Example 2A), the corresponding SNO-deoxyHb form can also be made by incubation of S-nitrosoglutathione or S-nitrosocysteine, for example, with Hb(FeII), yielding SNO-Hb(FeII), as in  
25 Example 1C.

The effects of the various forms of Hb on vasodilation -- constriction, dilation or a neutral effect -- depend on three factors: whether 1) the Fe of the heme is oxidized, 2) O<sub>2</sub> is bound at the heme (that is, the oxygenation state,  
30 dictated by the conformation of the protein as R state or T state), and 3) thiol is present in sufficient concentration to facilitate the transfer of NO<sup>+</sup>.

The importance of the first factor is shown in Figure 4A. Hb(FeII)O<sub>2</sub> and SNO-Hb[FeII]O<sub>2</sub> act as vasoconstrictors,  
35 but SNO-Hb[FeIII] (metHb form, where FeII has been oxidized

to FeIII) acts as a vasodilator. Figure 4A shows that SNO-Hb[FeII]O<sub>2</sub> with oxygen bound at the heme, and with a ratio of SNO/Hb=2, acts as a powerful vasoconstrictor.

SNO-Hb(FeII) is also a vasodilator. Figure 2B  
5 illustrates the second factor in demonstrating that rates of RSNO decomposition and transfer are much faster for SNO-Hb in the deoxy state than for SNO-Hb in the oxy state.

It can be seen how the NO<sup>+</sup>-donating properties of SNO-Hb depend on oxygen concentrations. SNO-Hb releases oxygen  
10 at sites of low oxygen concentration or under oxidizing conditions. SNO-Hb releases its NO group(s) to cause vasodilation either due to 1) oxidation of the heme Fe to FeIII or 2) loss of the O<sub>2</sub> from the heme by deoxygenation. It is shown in Figure 2B that NO is transferred off SNO-Hb  
15 best in the deoxy state. In ischemia, SNO-Hb deoxygenates, rapidly followed by the loss of NO. It can be seen from the data that SNO-metHb having a ratio of 1 SNO/SNO-metHb is a more powerful vasodilator than SNO-oxyHb having a ratio of 2 SNO/SNO-oxyHb. It should be noted that S-  
20 nitrosation of Hb induces the R state (oxy conformation). Thus, it follows that 1 SNO-oxyHb molecule having a ratio of 1 SNO/SNO-oxyHb is less potent than 10 molecules of SNO-oxyHb having a ratio of 0.1 SNO/SNO-oxyHb.

The third factor is illustrated by the results shown  
25 in Figure 4B. These results demonstrate potentiation by thiol of the vasodilator effect of SNO-Hb(FeII)O<sub>2</sub> and SNO-Hb(FeIII). Transfer of NO<sup>+</sup> from SNO-Hb to low molecular weight nitrosothiols is more efficient when Hb is in the deoxy state compared to the oxy state (Figure 2B) or in the  
30 met state compared to the oxy state (Figure 4C).

NO is released or transferred as NO<sup>+</sup> (nitrosyl cation) from SNO-Hb. The SNO groups of SNO-Hb have NO<sup>+</sup> character. Transfer of NO<sup>+</sup> from SNO-Hb occurs most efficiently to low molecular weight thiols, such as glutathione, and is most

efficient when the heme is oxidized (SNO-metHb) or the SNO-Hb is in the deoxy state.

One embodiment of the invention resulting from these findings is a method of therapy that enhances the transfer  
5 of NO<sup>+</sup> from SNO-Hb to low molecular weight thiols, thereby delivering NO biological activity to tissues, by the coadministration of low molecular weight thiols, along with a form of SNO-Hb, to a mammal in need of the physiological effects of NO. To further increase the effect of NO  
10 release it is preferred that the SNO- forms of metHb or deoxyHb (or an equivalent conformation or spin state) be administered with the thiol (See Figure 2B, for example.) A mixture of SNO-metHb and SNO-oxyHb, and possibly also thiol, can also be used. The composition and proportion of  
15 these components depends on the disease state. For example, to achieve both enhanced O<sub>2</sub> delivery and NO delivery, SNO-oxyHb can be used. Where no further delivery of O<sub>2</sub> is desirable, as in acute respiratory distress syndrome, for example, the SNO- forms of metHb and deoxyHb  
20 are especially preferred. Alternatively, the ratios of SNO/Hb can be regulated to control O<sub>2</sub> release.

A further invention arising out of the discoveries presented herein is a method for preserving a living organ  
ex vivo, for example for transplantation, comprising  
25 perfusing the organ with a composition comprising nitrosated hemoglobin and low molecular weight thiol or NO donating agent, wherein SNO-Hb(FeII)O<sub>2</sub> is a preferred nitrosated hemoglobin.

The vessel ring bioassay data of Figure 4A agree well  
30 with the *in vivo* data of Figure 5. The results of the experiments described in Example 5 confirm that Hb(FeII)O<sub>2</sub> (oxyHb) causes an increase in blood pressure *in vivo*, as it did also *in vitro*. SNO-Hb(FeIII) (SNO-metHb) causes a decrease in blood pressure *in vivo* as well as *in vitro*.  
35 SNO-Hb(FeII)O<sub>2</sub> (SNO-oxyHb) has a negligible effect on blood

pressure *in vivo* in contrast to the increase in tension seen in the corresponding vessel ring bioassay. For SNO-oxyHb the *in vivo* effect is neutral. This is explained by the constrictive effect caused by NO becoming bound to the heme being compensated by the release of NO upon deoxygenation. Therefore, SNO-oxyHb can deliver O<sub>2</sub> with minimal effect on blood pressure.

With knowledge of the results herein it is possible to synthesize Hb proteins with predicted NO-releasing properties, which will constrict, dilate, or have no effect on blood vessels. An additional option is the choice between making oxygenated or deoxygenated forms to administer for medical conditions in which O<sub>2</sub> delivery is desirable, or undesirable, respectively.

It is possible to produce a variety of modified Hbs having specific desired properties of O<sub>2</sub> and NO delivery. For example, Hb in the R state or R-structure (oxyHb) can be converted to the T state or T-structure (deoxyHb) by a number of known methods. This can be done, for example, by reaction of Hb with inositol hexaphosphate. It is also known to those skilled in the art that Hb in the R state can be made, for example, by treating Hb with carboxypeptidase. Similarly, it is known that metHb can be synthesized using ferricyanide or nitrite.

Producing Hb molecules which are locked in the T state allows the synthesis of RSNO-Hb which remains in a form that is a biologically active donor of NO, rather than a carrier of NO. Hb which is locked in the R state can be used as a substrate for the synthesis of RSNO-Hb which carries a maximum amount of NO per molecule.

Another embodiment of the invention is a blood substitute comprising one or more forms of Hb which have been specifically S-nitrosated to some extent at one or more thiol groups of the Hb, in order to regulate O<sub>2</sub> release and NO release. Conditions to be treated include

those in which NO or O<sub>2</sub> delivery is desired, those in which NO or O<sub>2</sub> utilization is desired, or those in which NO or O<sub>2</sub> is in excess. For example, in a medical condition which is characterized by the presence of an excess of oxygen free radicals and excess NO<sup>•</sup>, both the heme of SNO-Hb and NO released by SNO-Hb serve to trap oxygen free radicals. The heme Fe is oxidized in the process of scavenging oxygen free radicals and NO<sup>•</sup>, and NO is released from the oxidized Hb by donation to a thiol, in the form of RSNO<sup>+</sup>, which is not toxic. Inflammation and reperfusion injury, for example, are characterized by excess NO production and an excess of oxygen free radicals. Forms of Hb scavenge oxygen radicals and free NO, converting NO to forms that are not toxic.

A further embodiment of the invention is a method of therapy for a condition that would benefit from the delivery of NO in a biologically active form or O<sub>2</sub> or both, based on the administration of a blood substitute comprising a form of nitrosated Hb, such as S-nitrosohemoglobin, either alone or in combination with a low molecular weight thiol, for example. For example, SNO-Hb is useful to treat myocardial infarction. SNO-Hb has the effect of donating NO, keeping blood vessels open. SNO-Hb deoxygenates at low oxygen tension, delivering oxygen and releasing NO at the same site, thereby causing vasodilation. (See Example 7 and Figures 6A-6F.) These effects can be augmented by also administering thiol, either simultaneously with SNO-Hb, or before or after. For the purpose of treating myocardial infarction, for example, a high concentration or dose of SNO-Hb that has a low ratio of SNO/SNO-Hb is appropriate. Alternatively, SNO-metHb can be used for this purpose. A further application of these principals is a method for increasing cerebral blood flow in a mammal comprising administering to the mammal a

composition comprising S-nitrosohemoglobin, as illustrated in Figures 23A-23I.

In another aspect, the invention is a method of enhancing NO-donor therapy by coadministering a composition comprising SNO-Hb or other forms of nitrosated Hb together with a nitroso-vasodilator (nitroglycerin, for example) which would be otherwise consumed by the conversion of oxyHb to metHb in Hb which has not been S-nitrosated. A composition comprising a low molecular weight thiol can have the effect of producing a vasorelaxant response in a mammal (see Example 22 and Figure 20D).

Platelet activation is manifested by a number of events and reactions which occur in response to adhesion of platelets to a nonplatelet surface such as subendothelium. Binding of agonists such as thrombin, epinephrine, or collagen sets in motion a chain of events which hydrolyzes membrane phospholipids, inhibits adenylate cyclase, mobilizes intracellular calcium, and phosphorylates critical intracellular proteins. Following activation, platelets secrete their granule contents into plasma, which then allow the linking of adjacent platelets into a hemostatic plug. (See pages 348-351 in *Harrison's Principles of Internal Medicine*, 12th edition, eds. J.D. Wilson et al., McGraw-Hill, Inc., New York, 1991).

A thrombus is a pathological clot of blood formed within the circulatory system. It can remain attached to its place of origin or become dislodged and move to a new site within the circulatory system. Thromboembolism occurs when a dislodged thrombus or part of a thrombus partially or completely occludes a blood vessel and prevents oxygen transport to the affected tissues, ultimately resulting in tissue necrosis.

Sites where damage has occurred to the vascular surface are especially susceptible to the formation of thrombi. These sites include those on the interior surface

of a blood vessel in which damage to the endothelium, narrowing or stenosis of the vessel, or atherosclerotic plaque accumulation has occurred.

NO is one of several endothelium-derived  
5 thromboregulators, which are defined as physiological substances that modulate the early phases of thrombus formation. In particular, NO reduces platelet adhesion, activation and recruitment on the endothelial cell surface, and achieves this, it is thought, by activating platelet  
10 guanylate cyclase, thereby increasing platelet intracellular CGMP (Stamler, J.S. et al, *Circ. Res.* 65:789-795 (1989)), and decreasing intraplatelet  $Ca^{2+}$  levels. NO and the prostacyclin prostaglandin (PG)  $I_2$  act synergistically to inhibit and actively mediate platelet  
15 disaggregation from the collagen fibers of the subendothelial matrix. Unlike prostacyclin, NO also inhibits platelet adhesion. Furthermore, platelets synthesize NO, and the L-arginine-NO pathway acts as an intrinsic negative feedback mechanism to regulate platelet  
20 reactivity. NO is involved in leukocyte interactions with the vessel wall and can inhibit neutrophil aggregation. (See review article, Davies, M.G. et al., *British Journal of Surgery* 82:1598-1610, 1995.)

NO is antiathrogenic in a number of ways. (See, for  
25 example, Candipan, R.C. et al., *Arterioscler. Thromb. Vasc. Biol.* 16:44-50, 1996.) NO inhibits smooth muscle proliferation and attenuates LDL (low density lipoprotein) oxidation and other oxidant-related processes.

Hemoglobin may promote atherosclerosis as well as  
30 thrombosis as a consequence of its NO-scavenging property. This limitation of hemoglobin derives from its high affinity for nitric oxide. *In vitro*, NO is a potent inhibitor of platelet aggregation and adhesion to collagen fibrils, the endothelial cell matrix and monolayers  
35 (Radomski, M.W. et al., *Br. J. Pharmacol.* 92:181-187

(1987); Radomski, M.W. et al., *Lancet* 2:1057-1058 (1987);  
Radomski M.W. et al., *Biochem. Biophys. Res. Commun.*  
148:1482-1489 (1987)). NO elevates cGMP levels in  
platelets, thereby decreasing the number of platelet-bound  
5 fibrinogen molecules and inhibiting intracellular  $\text{Ca}^{++}$  flux  
and platelet secretion (Mellion, B.T. et al., *Blood* 57:946-  
955 (1981); Mendelson, M.E. et al., *J. Biol. Chem.*  
165:19028-19034 (1990); Lieberman, E. et al., *Circ. Res.*  
68:1722-1728 (1991)). Scavenging of nitric oxide by Hb  
10 prevents the molecule from inhibiting platelets. This  
explanation has been given support by *in vivo* studies  
(Krejcy, K. et al., *Arterioscler. Thromb. Vasc. Biol.*  
15:2063-2067 (1995)).

The results shown in Figures 7A-7C (see Example 9)  
15 show that nitrosated hemoglobins, including SNO-Hb, can be  
used in the treatment of acute blood clotting events that  
occur as a result of increased platelet deposition,  
activation and thrombus formation or consumption of  
platelets and coagulation proteins. Such complications are  
20 known to those of skill in the art, and include, but are  
not limited to myocardial infarction, pulmonary  
thromboembolism, cerebral thromboembolism, thrombophlebitis  
and unstable angina, and any additional complication which  
occurs either directly or indirectly as a result of the  
25 foregoing disorders.

SNO-Hb and other nitrosated hemoglobins can also be  
used prophylactically, for example, to prevent the  
incidence of thrombi in patients at risk for recurrent  
thrombosis, such as those patients with a personal history  
30 or family history of thrombosis, with atherosclerotic  
vascular disease, with chronic congestive heart failure,  
with malignancy, or patients who are pregnant or who are  
immobilized following surgery.

NO is known to activate soluble guanylate cyclase,  
35 which produces cGMP. cGMP mediates inhibition of platelet

aggregation. Results in Example 10 demonstrate that this inhibition of platelet aggregation may be mediated not by cGMP alone, but by some other mechanism as well.

Certain compounds or conditions are known to cause a shift in the allosteric equilibrium transition of Hb towards either of the two alternative quaternary structures of the tetramer, the T- or R-structures. (See, for example, pages 7-28 in Perutz, M., *Mechanisms of Cooperativity and Allosteric Regulation in Proteins*, Cambridge University Press, Cambridge, U.K., 1990.) These are, for instance, the heterotropic ligands  $H^+$ ,  $CO_2$ , 2,3-diphosphoglycerate (2,3-DPG) and  $Cl^-$ , the concentrations of which modulate oxygen affinity. The heterotropic ligands lower the oxygen affinity by forming additional hydrogen bonds that specifically stabilize and constrain the T-structure. Other compounds affecting the allosteric equilibrium include inositol hexaphosphate (IHP) and the fibric acid derivatives such as bezafibrate and clofibrate. The fibric acid derivatives, antilipidemic drugs, have been found to combine with deoxy-, but not with oxyhemoglobin. They stabilize the T-structure by combining with sites in the central cavity that are different from the DPG binding sites. Other allosteric effectors have been synthesized which are related to bezafibrate. A ligand that stabilizes specifically the R-structure increases the oxygen affinity, and a ligand that stabilizes the T-structure does the reverse. Other ligands can affect the spin state of the heme. For example, in deoxyhemoglobin and in methemoglobin the Fe is high-spin ferrous ( $S=2$ ) and 5-coordinated; in oxyhemoglobin and in cyan-metHb the Fe is low-spin ferrous ( $S=0$ ) and 6-coordinated; when  $H_2O$  is the sixth ligand, methemoglobin is also high-spin. The inhibition of platelet aggregation by S-nitroso-methemoglobin seen in Figure 7C is consistent with enhanced potency in the high spin conformation. Substances which control the allosteric

equilibrium or spin state of hemoglobin can be administered in a pharmaceutical composition to a human or other mammal, in a therapeutically effective amount, to promote the formation of, or to stabilize, a particular allosteric structure and/or spin state of hemoglobin, thereby regulating platelet activation, e.g., by converting hemoglobin from R-structure to T-structure.

The dosage of Hb required to deliver NO for the purpose of platelet inhibition can be titrated to provide effective amounts of NO without causing drastic changes in blood pressure. If the goal of the therapy is to deliver oxygen, the Hb can be administered in a unit of blood to avoid a drop in blood pressure. If the goal is to alleviate shock, very little Hb can be administered compared to the amount to be given for myocardial infarction. For shock, the more important goal is to deliver NO rather than to deliver oxygen. For this objective, it can be preferable to use continuous infusion or several infusions per day. Example 12 (see Figure 10) shows that the effects of SNO-Hb(FeII)O<sub>2</sub> on blood flow in rat brain last over 20 minutes; in other experiments an effect has been seen for up to an hour. There is a correlation between blood pressure effects and platelet inhibition effects, but platelet inhibition occurs at a lower NO concentration than that which is required to produce blood pressure effects, and generally lasts longer.

Example 11 shows that S-nitrosothiols can be used to add NO groups not only on the thiol groups of cysteine residues in hemoglobin, but also on other reactive sites of the hemoglobin molecule. The products of the nitrosation reactions in Example 11 were hemoglobin molecules with more than 2 NO groups per Hb tetramer. The exact sites of the addition of NO have not been confirmed, but it is expected that NO addition occurs at thiol groups and various other nucleophilic sites within Hb, including metals. Reactive

sites, after the thiol groups, are tyrosine residues and amines, and other nucleophilic centers.

Nitrosation reactions on other proteins have been investigated previously (Simon, D.I. et al., *Proc. Natl. Acad. Sci. USA* 93:4736-4741 (1996)). Methods of modifying proteins to produce nitrosoproteins are known in the art, and include, for example, exposing the protein to  $\text{NaNO}_2$  in 0.5 M HCl (acidified  $\text{NO}_2^-$ ) for 15 minutes at  $37^\circ\text{C}$ . An alternative method is to place a helium-deoxygenated solution of protein in 100 mM sodium phosphate, pH 7.4, inside dialysis tubing and expose the protein to NO gas bubbled into the dialysate for 15 minutes. (Stamler, J.S. et al., *Proc. Natl. Acad. Sci. USA* 89:444-448 (1992); see also Williams, D.L.H. *Nitrosation*, Cambridge University Press, New York (1988), which gives further methods of nitrosation).

By these methods, multiple NO-related modifications ("NO groups" or "NO biological equivalents" resulting from nitrosations, nitrosylations or nitrations) can be made on Hb at nucleophilic sites, which can include thiols, nucleophilic oxygen atoms as found in alcohols, nucleophilic nitrogen atoms as found in amines, or the heme iron. Agents facilitating nitrosations, nitrosylations or nitrations of Hb can be thought of as "NO or  $\text{NO}^+$  donating agents." The products of such modifications may have such groups, for example, as -SNO, -SNO<sub>2</sub>, -ONO, ONO<sub>2</sub>, -CNO, -CNO<sub>2</sub>, -NNO, -NNO<sub>2</sub>, -FeNO, -CuNO, -SCuNO, SFeNO and the different ionized forms and oxidation variants thereof. (See, regarding oxidation of hemoglobin by  $\text{Cu}^{++}$ , Winterbourne, C., *Biochemistry J.* 165:141-148 (1977)). The covalent attachment of the NO group to sulfhydryl residues in proteins is defined as S-nitrosation; the covalent attachment of the NO group to a metal, such as Fe, can be called nitrosylation, yielding a metal-nitrosyl complex. General NO attachment to nucleophilic centers is referred

to herein as nitrosation. Thus, the term nitrosated hemoglobin as used herein includes SNO-Hb and Hb(FeII)NO as well as other forms of hemoglobin nitrosated at other sites in addition to thiols and metals. In addition, Hb can be  
5 nitrated. Hbs which have been nitrosated and/or nitrated at multiple different types of nucleophilic sites (termed polynitrosated, that is, having NO equivalents added to other nucleophilic sites as well as to thiols; or polynitrated, respectively) will permit transnitrosation  
10 reactions and the release of NO and its biological equivalents in the circulatory system at different rates and engendering different potencies.

These and other nitrosation and nitration reactions can cause oxidation of the heme Fe to some extent, under  
15 some conditions. However, some minor degree of oxidation is acceptable. The nitrosated Hb is still be useful as a therapeutic agent if oxidized to a minor extent. For applications where the NO-delivering function, rather than the O<sub>2</sub>-delivering function of nitrosated Hb, is more  
20 desirable, extensive oxidation of the heme Fe is acceptable.

If it is desired to avoid oxidation of the heme Fe, it is possible to remove the heme, perform the necessary chemical reactions upon the protein to nitrosate to the  
25 extent desired, and replace the heme into the modified hemoglobin product. (See, for removing and replacing the heme, Antonini, E. and Brunori, M., *Hemoglobin and Myoglobin in their Reactions with Ligands*, Elsevier, New York, 1971.)

30 In addition to the nitrosating under conditions that do not oxidize the heme, such as brief exposure to low molecular weight RSNOs, as illustrated in Examples 1 and 2, alternative methods can be used to produce nitrosated hemoglobin in which the heme Fe is not oxidized. For  
35 instance, it is possible to produce by recombinant methods

$\alpha$  and  $\beta$  globin chains, nitrosate them to the extent desired, then assemble the chains with heme to form a functional, nitrosated tetramer. (See, for example, European Patent Application EPO 700997, published March 13, 1996, "Production in bacteria and yeast of hemoglobin and analogues thereof.")

Another alternative method to nitrosate the  $\alpha$  and  $\beta$  globin chains without producing a form of metHb as the end product, is to nitrosate the intact Hb molecule to the extent desired, thereby allowing the heme Fe to be oxidized, then reduce the heme Fe from FeIII to FeII by treating the nitrosated Hb with either methemoglobin reductase or a cyanoborohydride such as sodium cyanoborohydride.

It has been generally thought that nitric oxide as NO gas in solution reacts with hemoglobin (Hb) in two major ways: 1) with the deoxyHb to form a stable nitrosyl (FeII) heme adduct; and 2) with oxyHb to form nitrate and metHb -- a reaction that inactivates NO. These two reactions contributed to the idea that Hb is a scavenger of NO. In both of these reactions, NO biological activity is lost. The results described herein demonstrate that, in fact, neither reaction occurs under physiological conditions. Rather, the products of the NO/Hb reaction are dictated by the ratio of NO to Hb, and by the conformation of Hb -- R(oxy) vs. T(deoxy).

At low ratios of NO to deoxyHb (e.g., 1:100 or less), the Hb molecule is in T-structure. Under this condition, NO introduced as gas to a Hb solution binds to the  $\alpha$ -hemes, as has been seen by EPR. Upon introduction of oxygen, with conversion to the R state, NO is transferred to a thiol of cysteine to yield S-nitrosohemoglobin with close to 100% efficiency. At ratios of NO/Hb of 1:25-1:50, the efficiency of formation of SNO-Hb is ~35% (decreasing with increasing NO/Hb ratio). The reaction appears to involve

migration of NO from  $\alpha$  heme to  $\beta$  heme and then to the  $\beta$  thiol. In going from the heme to a thiol, the heme or nitrosothiol needs to lose an electron by oxidation ( $\text{NO} \rightarrow \text{NO}^+$  or  $\text{RSNO} \cdot \rightarrow \text{RSNO}$ ). Oxygen serves as an electron  
5 acceptor in the system, driving the reaction thermodynamically, as well as causing a conformational change by its binding at the heme, which exposes the thiol groups. At higher ratios of NO to Hb (1:20-1:2), with the protein still in T-structure, the protein liberates  $\text{NO}^-$   
10 from the  $\beta$  hemes with production of metHb. This occurs in the absence of  $\text{O}_2$  and provides another indication that the NO bound to  $\beta$ -hemes is unstable. Once  $\text{O}_2$  is introduced, S-nitrosothiol (SNO) forms, but the relative yield is very low because of loss to  $\text{NO}^-$ . The yield of SNO-Hb approaches  
15 zero at NO/Hb ratios of 1:2, upon introduction of oxygen.

At the higher ratios of NO to Hb (i.e., >0.75-1), NO itself maintains the R-structure. Under this condition, the NO is more stable because of an unusual constraint on the molecule. Specifically, loss of NO from the  $\beta$  hemes  
20 promotes the T-structure, whereas formation of SNO-Hb selects for the R-structure. This is not a favored reaction. The consequence is that small amounts of S-nitrosohemoglobin are formed, but the yields are low (~5%). This does not exclude the possibility that the molecule has  
25 therapeutic value.

The reaction of NO with oxyHb is also dependent on the ratios of NO to oxyHb. Under conditions of relatively high (non-physiological) ratios of NO to Hb, ( $\text{NO}/\text{oxyHb} > 1:20$ ), NO appears to destabilize the hydrogen bond between the  $\text{O}_2$   
30 and the proximal histidine (by competing for it) yielding some metHb. By changing the ionic composition of the solvent buffer (e.g., borate 0.2 M, pH 7.4), formation of metHb can be significantly reduced even with excess NO ( $\text{NO}/\text{Hb} = 3:1$ ). On the other hand, metHb formation is  
35 facilitated in acetate buffer at pH 7.4; when the hydrogen

bond between O<sub>2</sub> and the proximal histidine is broken, the O<sub>2</sub> seems to gain superoxide-like character. NO then reacts rapidly to form metHb and nitrate. Efficient metHb formation actually requires an excess of NO/oxyHb. In contrast, at lower ratios of NO/Hb (<1:20), it reacts with the small residual fraction (<1%) of deoxyHb, in turn producing S-nitroso-hemoglobin extremely efficiently. As the concentration of NO is increased, there is some reaction with oxyHb, but the products are nitrite and nitrate, not nitrate alone. The conclusion is that NO can be incubated in reaction mixtures of oxyHb without inactivating the O<sub>2</sub> binding functionality by converting it to nitrate.

Nitrosylhemoglobin can be used in an animal or human as a therapeutic NO donor for the prevention or treatment of diseases or medical disorders which can be alleviated by delivery of NO or its biologically active form to tissues affected by the disease or medical disorder. Like SNO-Hb, nitrosylhemoglobin can be administered as a blood substitute, because nitrosylhemoglobin can be converted to SNO-Hb under physiological conditions. NO is released from the thiol either by deoxygenation or by conversion to metHb.

Inhaled NO causes selective pulmonary vasodilation without influencing systemic responses. A previously-formed rationale behind its use is that scavenging by Hb prevents adverse systemic effects. It is illustrated in Examples 14-21 that NO can be used to produce S-nitrosohemoglobin, which is a potent vasodilator and antiplatelet agent. Inhaled NO can be used to raise levels of endogenous S-nitrosohemoglobin. Similarly, treatment of red blood cells (RBCs) with NO can be used to form SNO-RBCs, or "loaded" red blood cells.

Compared to SNO-deoxyHb, which is a good NO donor, but which would release its NO very quickly, or SNO-oxyHb,

which would release its NO more slowly, but has a propensity to form metHb over time, nitrosyl-deoxyhemoglobin stored in a form such that final ratio of NO:heme is less than about 1:100 or greater than about 0.75, is stable. Formation of metHb is prevented at these NO:heme ratios. For this reason nitrosyl-deoxyhemoglobin stored with such NO:heme ratios in a physiologically compatible buffer can be administered to an animal or human as an NO donor. Erythrocytes comprising nitrosylhemoglobin can also be used as NO donors. Erythrocytes comprising nitrosylhemoglobin can be made in a process comprising incubating deoxygenated erythrocytes in a solution comprising NO.

A blood substitute or therapeutic which can be used as an NO donor, and which is free of the vasoconstrictor effects of underviatized Hbs, can be made by obtaining a solution of oxyHb (including solutions stored in the form of oxyHb) and adding NO as dissolved gas, yielding SNO-oxyHb. Buffer conditions and NO:Hb ratios can be optimized, as illustrated in Example 21 and Figure 19, to yield S-nitrosothiol without significant production of oxidized Hb (metHb). For example, NO added to oxyhemoglobin in 10 mM phosphate buffer, pH 7.4, at a ratio of less than 1:30 NO:Hb resulted in formation of SNO-oxyHb with minimal formation of metHb. This ratio can be increased by varying the buffer conditions, for example by the use of 10 mM phosphate, 200 mM borate at pH 7.4. The buffer anions as well as the buffer concentration should be chosen carefully. For instance, acetate and chloride have the opposite effect from borate, increasing the formation of metHb and nitrite at 200 mM, pH 7.4.

This can be explained by a competition between free NO and oxygen for a H-bond with the imidazole of the proximal His residue. If low concentrations of NO are used, in low ionic strength buffer, e.g., 10 mM phosphate, metHb does

not readily form. If the H-bond is weakened by increasing the ionic strength of the buffer, NO reacts more readily with oxyHb, yielding more metHb. Buffers with a low  $pK_a$  relative to pH 7.4 tend to stabilize FeIII. Buffers having  
5 a  $pK_a$  at least about two pH units higher than the reaction condition are preferred.

A blood substitute can be made which acts as a donor of  $NO^-$ . NO can be added to a solution of deoxyHb at a ratio of NO:Hb in the range of 1:100 to 1:2, with a ratio  
10 of NO/heme of approximately 1:10 being preferred. If the ratio of NO:heme is increased, to a NO:Hb of about 2 (at which Hb is still in the T (deoxy) state), in the absence of an electron acceptor/free radical scavenger, NO is released from the  $\beta$  heme as  $NO^-$ , with oxidation of the heme  
15 iron to form metHb. The product solution can be used as a blood substitute or a therapeutic NO donor.  $NO^-$  can protect from N-methyl-D-glutamate-mediated brain injury in stroke; this effect has not been found for NO.

Nitrosylhemoglobin belongs to a broader class of  
20 nitrosyl-heme-containing donors of NO which can be administered to an animal or human for the delivery of NO to tissues. Nitrosyl-heme-containing donors of NO include, for example, the nitrosated ("nitrosated" as defined herein) hemoglobins nitrosylhemoglobin and SNO-  
25 nitrosylhemoglobin, nitrosyl-heme, and substituted forms of hemoglobin in which a different metal, (e.g.,  $Co^{++}$ ,  $Mg^{++}$ ,  $Cu^{++}$ ) is substituted for the heme iron, or nitrosyl-porphyrins are substituted for the heme.

Applicants teach physiologically significant results  
30 that provide a rationale for NO donors to be attached to Hb. Such derivatized Hbs can themselves serve as NO-donating therapeutics and can ameliorate the side effects of underivatized Hb administered as a blood substitute, for example. At one time, it had been thought that there would  
35 be no use for these compounds, because it was thought that

NO released by the Hb would immediately be scavenged by the heme. It had been thought also that the released NO would oxidize Hb and limit oxygen delivery. The same rationale has previously limited the administration of NO donors,  
5 such as nitroglycerin and nitroprusside, because they had been thought to cause the formation of methHb.

Preferably, NO-donors to be covalently attached to hemoglobin are relatively long-lived and have at least one functional group that can be used for the chemical  
10 attachment to hemoglobin. Examples of NO-donors include nitroprusside, nitroglycerin, nitrosothiols, and the diazeniumdiolate class of compounds (also called "NONOates") having structure 1.

A variety of these compounds have been synthesized that, in their anionic form, release NO without activation at physiological pH (Keefer, L.K. et al., *Am. Chem. Soc. Symposium Ser.* 553:136-146 (1994); Hanson, S.R. et al., *Adv. Pharmacol.* 34:383-398 (1995)). Systemic  
20 administration can result in system-wide effects, according to equation 1. However, attachment to hemoglobin can be used to produce tissue-selective delivery of NO and oxygen.  
25 For instance, covalently esterified NO-donors can be activated predominantly in the liver. Different NO donors can be chosen to be linked to hemoglobin for different controlled release rates of NO from Hb.

Compound 4 (below), for example, is a diazeniumdiolate  
30 with a half-life for NO release, at 37°C and pH 7.4, of approximately two weeks. It can be converted to its nucleophilic N-4 mercaptoethyl derivative, compound 5. Hemoglobin can be activated toward coupling reactions by

reacting it with  $\gamma$ -maleimidobutyric acid *N*-hydroxysuccinimide ester. Compound 5 can then be covalently attached to the activated hemoglobin through its maleimide functionality. The adduct, 6, can generate NO steadily over several days in pH 7.4 phosphate buffer at 37°C. This property can alleviate side effects of underivatized blood substitutes, for example.

4: R = H-

5: R = HSCH<sub>2</sub>CH<sub>2</sub>-

Nitric oxide synthase (NOS) working in conjunction with Hb can reload NO onto the hemes, thus a composition comprising NOS and Hb, or NOS conjugated to Hb can facilitate delivery of NO to the tissues. NOS of neurons  
5 is preferable for this composition because the neuronal NOS responds to oxygen tension. At low oxygen tension, the neuronal NOS produces more NO; at high oxygen tension, NOS produces less NO. This form of NOS will efficiently reload NO onto the heme when Hb is deoxygenated. NOS-Hb  
10 conjugates can be used when a blood substitute is indicated, and especially when an ischemic injury or condition is present.

Biologically compatible electron acceptors, are well known in the art and include, but are not limited to,  
15 superoxide dismutase and the oxidized forms of nicotinamide adenine dinucleotide (NAD<sup>+</sup>), nicotinamide adenine dinucleotide phosphate (NADP<sup>+</sup>), flavin adenine dinucleotide (FAD), flavin mononucleotide (FMN), ascorbate, dehydroascorbate and nitroxide spin traps. One or more  
20 electron acceptors can be conjugated to Hb molecules, and can facilitate the conversion of the nitrosyl-Hb-electron acceptor form to the SNO-Hb-electron acceptor form by accepting the electron lost by NO in its transfer, in the form of NO<sup>+</sup> or as RSNO<sup>•</sup>, to a  $\beta$ 93Cys thiol group.

25 Nitroxides are one such class of electron acceptors which also act as free radical scavengers. Nitroxides are stable free radicals that have been shown to have antioxidant catalytic activities which mimic those of superoxide dismutase (SOD), and which when existing in  
30 vivo, can interact with other substances to perform catalase-mimic activity. Nitroxides have been covalently attached to hemoglobin. See Hsia, J-C., U.S. Serial No. 5,591,710, the contents of which are incorporated by reference in their entirety. See also Liebmann, J. et al.,  
35 *Life Sci.* 54:503-509 (1994), describing nitroxide-

conjugated bovine serum albumin and differential nitroxide concentrations among the different organs of mice tested with the conjugate.

Methods for chemically attaching superoxide dismutase  
5 (SOD) to Hb are known in the art. For example, see Quebec,  
E.A. and T.M. Chang, *Artif. Cells Blood Substit. Immobil. Biotechnol.* 23:693-705 (1995) and D'Agnillo, F. and Chang,  
T.M., *Biomater. Artif. Cells Immobilization Biotechnol.*  
21:609-621 (1993). SOD attached to nitrosylhemoglobin can  
10 drive the reaction in which NO is transferred from the heme  
to thiol, by serving as an electron acceptor.

Like NO, CO is known to have vasodilator effects.  
(See Zakhary, R. et al., *Proc. Natl. Acad. Sci USA* 93:795-  
798 (1996).) A solution of deoxyhemoglobin can be  
15 derivatized with CO by exposing it to purified CO gas in  
solution, until the desired extent of CO-bound Hb is  
reached. CO-derivatized Hb can be administered as a blood  
substitute or co-administered with other heme-based blood  
substitutes to alleviate the effects (e.g., hypertension,  
20 intestinal pain and immobility) of underivatized  
hemoglobin. Hemoglobins can be derivatized to the extent  
necessary to overcome constrictor effects, for example to a  
ratio of CO/Hb in the range of approximately 0.1% to 10%.

Because the  $\alpha$  subunits lack thiol groups to serve as  
25 NO<sup>+</sup> acceptors from the heme, a blood substitute comprising  
 $\alpha$  chains, for example in the form of dimers or tetramers,  
can be made which has different properties from a blood  
substitute comprising  $\beta$  chains alone, or comprising a  
combination of  $\alpha$  and  $\beta$  chains. A blood substitute  
30 comprising  $\alpha$  chains of hemoglobin can be administered to an  
animal or to a human patient to alleviate a condition  
characterized by the effects caused by NO, for example, in  
hypotensive shock.

$\beta$  chains, unlike  $\alpha$  chains, serve as active donors of  
35 NO to the tissues, rather than traps for NO. A blood

substitute comprising  $\beta$  chains, for example in the form of  $\beta$  dimers or tetramers, can be made. Such a blood substitute can be administered to a mammal to treat diseases or medical disorders wherein it is desired to  
5 deliver oxygen as well as NO or its biological equivalent to tissues affected by the disease, for example, in angina and other ischemic conditions.

Methods are known by which hemoglobin can be separated into its  $\alpha$  and  $\beta$  subunits and reconstituted. Separated,  
10 heme-free, alpha- and beta-globins have been prepared from the heme-containing alpha and beta subunits of hemoglobin. (Yip, Y.K. et al., *J. Biol. Chem.* 247:7237-7244 (1972)). Native human hemoglobin has been fully reconstituted from separated heme-free alpha and beta globin and from hemin.  
15 Preferably, heme is first added to the alpha-globin subunit. The heme-bound alpha globin is then complexed to the heme-free beta subunit. Finally, heme is added to the half-filled globin dimer, and tetrameric hemoglobin is obtained (Yip, Y.K. et al., *Proc. Natl. Acad. Sci. USA*  
20 74:64-68 (1977)).

The human alpha and beta globin genes reside on chromosomes 16 and 11, respectively. Both genes have been cloned and sequenced, (Liebhaber, et al., *Proc. Natl. Acad. Sci. USA* 77:7054-7058 (1980) (alpha-globin genomic DNA);  
25 Marotta, et al., *J. Biol. Chem.* 252:5040-5053 (1977) (beta globin cDNA); Lawn, et al., *Cell* 21:647 (1980) (beta globin genomic DNA)).

Recombinant methods are available for the production of separate  $\alpha$  and  $\beta$  subunits of hemoglobin. For instance,  
30 Nagai and Thorgeron, (*Nature* 309:810-812 (1984)) expressed in *E. coli* a hybrid protein consisting of the 31 amino terminal residues of the lambda cII protein, an Ile-Glu-Gly-Arg linker, and the complete human beta globin chain. They cleaved the hybrid immediately after the linker with  
35 blood coagulation factor Xa, thus liberating the beta-

globin chain. Later, (Nagai, K. et al., *Proc. Natl. Acad. Sci. USA* 82:7252-7255 (1985)) took the recombinant DNA-derived human beta globin, naturally derived human alpha globin, and a source of heme and succeeded in producing  
5 active human hemoglobin.

An efficient bacterial expression system for human alpha globin was reported. (GB 8711614, filed May 16, 1987; see also WO 88/09179). This led to the production of wholly synthetic human hemoglobin by separate expression of  
10 the insoluble globin subunits in separate bacterial cell lines, and *in situ* refolding of the chains in the presence of oxidized heme cofactor to obtain tetameric hemoglobin. A synthetic human hemoglobin has been produced in yeast cells (EP 700997A1, filing date 10.05.1990).

15 The properties of hemoglobin have been altered by specifically chemically crosslinking the alpha chains between the Lys99 of alpha 1 and the Lys99 of alpha 2. (Walder, U.S. 4,600,531 and 4,598,064; Snyder, et al., *Proc. Natl. Acad. Sci USA* 84:84 7280-7284 (1987);  
20 Chatterjee, et al., *J. Biol. Chem.* 261:9927-9937 (1986)). This chemical crosslinking was accomplished by reacting bis (3,5-dibromosalicyl) fumarate with deoxyhemoglobin A in the presence of inositol hexaphosphate. The beta chains have also been chemically crosslinked. (Kavanaugh, M.P. et al.,  
25 *Biochemistry* 27:1804-1808 (1988)). Such linking methods or other suitable methods can be adapted to methods of producing  $\alpha$  or  $\beta$  dimers or other multimers, or for the crosslinking of other polypeptides to the  $\alpha$  and  $\beta$  chains. (For further methods to derivatize proteins and to  
30 conjugate proteins, see Hermansoh, G.T., *Bioconjugate Techniques*, Academic Press, 1996.)

The term hemoglobin or Hb as used herein includes variant forms such as natural or artificial mutant forms differing by the addition, deletion and/or substitution of  
35 one or more contiguous or non-contiguous amino acid

residues, or modified polypeptides in which one or more residues is modified, and mutants comprising one or more modified amino acid residues. Hb also includes chemically modified forms as well as genetically altered forms, such as fusion proteins, and truncated forms. It also includes Hbs of all animal species and variant forms thereof. The biological and/or chemical properties of these variant Hbs can be different from those of hemoglobins which are found naturally occurring in animals.

10 It will be appreciated that NO exists in biological systems not only as nitric oxide gas, but also in various redox forms and as biologically active adducts of nitric oxide such as S-nitrosothiols, which can include S-nitrosoproteins, S-nitroso-amino acids and other S-nitrosothiols (Stamler, J.S. *Cell* 78:931-936 (1994)).

15 A blood substitute can be a biologically compatible liquid which performs one or more functions of naturally occurring blood found in a mammal, such as oxygen carrying and/or delivery, NO carrying and/or delivery, and the scavenging of free radicals. A blood substitute can also comprise one or more components of such a liquid which, when infused into a mammal, perform one or more functions of naturally occurring blood. Examples of blood substitutes include preparations of various forms of hemoglobin. Such preparations can also include other biologically active components, such as a low molecular weight thiol, nitrosothiol or NO donating agents, to allow transnitrosation. Low molecular weight thiols (i.e., relative to proteins and other biological macromolecules) can include glutathione, cysteine, N-acetylcysteine, S-nitrosocysteinyglycine, S-nitrosocysteine, and S-nitrosohomocysteine.

25 The compounds and therapeutic preparations of this invention to be used in medical treatment are intended to be used in therapeutically effective amounts, in suitable

compositions, which can be determined by one of skill in the art. Modes of administration are those known in the art which are most suitable to the affected site or system of the medical disorder. Intravenous infusion is a preferred mode of administration of various forms of hemoglobin to be used as a blood substitute. Suitable compositions can include carriers, stabilizers or inert ingredients known to those of skill in the art, along with biologically active component(s).

10       The term "therapeutically effective amount," for the purposes of the invention, refers to the amount of modified Hb and/or nitrosating agent which is effective to achieve its intended purpose. While individual needs vary, determination of optimal ranges for effective amounts of  
15       each compound to be administered is within the skill of one in the art. Research animals such as dogs, baboons or rats can be used to determine dosages. Generally, dosages required to provide effective amounts of the composition or preparation, and which can be adjusted by one of ordinary  
20       skill in the art, will vary, depending on the age, health, physical condition, sex, weight, extent of disease of the recipient, frequency of treatment and the nature and scope of the desired effect. Dosages for a particular patient can be determined by one of ordinary skill in the art using  
25       conventional considerations, (e.g. by means of an appropriate, conventional pharmacological protocol). For example, dose response experiments for determining an appropriate dose of a heme-based blood substitute can be performed to determine dosages necessary to produce a  
30       physiological concentration of approximately 1 nM to 100  $\mu$ M heme. Suitable pharmaceutical carriers or vehicles can be combined with active ingredients employed in a therapeutic composition, if necessary.

The present invention is further and more specifically illustrated in the following examples, which are not intended to be limiting in any way.

#### EXEMPLIFICATION

##### 5 Materials and Methods for Assays

###### *Determination of R-S-NO Concentration*

The concentration of R-S-NO groups in a sample is based on the method reported in Saville, *Analyst* 83:670-672 (1958). The quantification of the NO group, displaced from  
10 the thiol by mercuric ion, forms the basis of this highly sensitive method. The detection limit is in the range of 0.1-0.5  $\mu\text{M}$ .

As shown (equations 5-7), the reaction proceeds in two steps. First,  $\text{NO}^+$  is displaced from the RSNO by mercuric ion and reacts, under acidic conditions, with sulfanilamide ( $\text{Ar-NH}_2$ ). In a second step, the diazonium salt (which is  
20 formed in amounts equivalent to the thionitrite) is then coupled with the aromatic amine, N-(1-naphthyl)-ethylenediamine ( $\text{Ar}'$ ), to form an intensely colored azo dye which can be measured at 540 nm ( $\epsilon \sim 50,000 \text{ M}^{-1} \text{ cm}^{-1}$ ). The same assay performed with the mercuric salt omitted allows  
25 for the simultaneous detection of nitrite. In principle, the second part of the Saville procedure is analogous to the classical Griess reaction for the detection of nitrite.

The procedure is as follows:

Solution A: sulfanilamide 1% dissolved in 0.5 M HCl.

30 Solution B: same solution as used in A to which 0.2%  $\text{HgCl}_2$

Solution C: 0.02% solution of *N*-(1-naphthyl)-ethylenediamine dihydrochloride dissolved in 0.5 M HCl.

A given volume (50  $\mu$ l-1ml) of the sample to be assayed is added to an equivalent volume of solution A and solution  
5 B. The two samples are set aside for 5 minutes to allow formation of the diazonium salt, after which an equivalent volume of solution C is added to each mixture. Color formation, indicative of the azo dye product, is usually complete by 5 minutes. The sample absorbance is then read  
10 spectrophotometrically at 540 nm. The RSNO is quantified as the difference in absorbance between solution B and A. (i.e. B - A). In the event that the background nitrite concentration is high (i.e. increased background in A), the accuracy of the measurement can be increased by the  
15 addition of an equivalent volume of 0.5% ammonium sulfamate in acid (45 mM) 5 minutes prior to the addition of sulfanilamide. The nitrous acid in solution reacts immediately with excess ammonium sulfamate to form nitrogen gas and sulfate.

20 Concentrations of thiol greater than 500  $\mu$ M in samples may interfere with the assay if nitrite is also present at micromolar concentration. Because nitrite will nitrosate indiscriminantly under the acidic conditions employed, thiols will effectively compete for reaction with  
25 sulfanilamide (present at 50 mM in this assay) as their concentration approaches the millimolar range. This will lead to artifactual detection of RSNO. The problem can be avoided by (1) keeping the ratio of thiol to sulfanilamide < 0.01, (2) first alkylating thiols in the solution, or (3)  
30 adding free thiols to standards to correct for the potential artifact.

#### *Assay for S-nitrosohemoglobin and Nitrosyl (FeII) -Hemoglobin*

A highly sensitive photolysis-chemiluminescence methodology was employed, which had been used for measuring

RSNOs (S-nitrosothiols) in biological systems (Gaston, B.,  
et al., *Proc. Natl. Acad. Sci. USA* 90:10957-10961 (1993);  
Stamler, J.S., et al., *Proc. Natl. Acad. Sci. USA* 89:7674-  
7677 (1992)). The method involves photolytic liberation of  
5 NO from the thiol, which is then detected in a  
chemiluminescence spectrometer by reaction with ozone. The  
same principle of operation can be used to cleave (and  
measure) NO from nitrosyl-metal compounds (Antonini, E. and  
Brunori, M. *In Hemoglobin and Myoglobin in Their Reactions*  
10 *with Ligands*, American Elsevier Publishing Co., Inc., New  
York, pp. 29-31 (1971)). With adjustment of flow rates in  
the photolysis cell, complete photolysis of the NO ligand  
of Hb(FeII)NO is achieved. Standard curves derived from  
synthetic preparations of SNO-Hb, Hb(FeII)NO, and S-  
15 nitrosogluthathione were linear ( $R > 0.99$ ), virtually  
superimposable, and revealing of sensitivity limits of  
approximately 1 nM. Two analytical criteria were then  
found to reliably distinguish SNO-Hb from Hb(FeII)NO:  
1) signals from SNO-Hb were eliminated by pretreatment of  
20 samples with 10-fold excess  $HgCl_2$ , while Hb(FeII)NO was  
resistant to mercury challenge; and 2) treatment of SNO-Hb  
with  $HgCl_2$  produced nitrite (by standard Griess reactions)  
in quantitative yields, whereas similar treatment of  
Hb(FeII)NO did not. UV/VIS spectroscopy confirmed that NO  
25 remained attached to heme in the presence of excess  $HgCl_2$ .

We linked a photolysis cell directly to the reaction  
chamber and detector portion (bypassing the pyrolyzer) of a  
chemiluminescence apparatus (model 543 thermal energy  
analyzer, Thermedix, Woburn MA). A sample (5 to 100  $\mu l$ ) is  
30 either introduced directly or introduced as a  
chromatographic effluent from an attached high-performance  
liquid or gas chromatography system into the photolysis  
cell (Nitrolite, Thermedix, Woburn MA). This cell consists  
of a borosilicate glass coil (3 m x 0.64 cm o.d. x 1 mm  
35 i.d., turned to a diameter of 6 cm and a width of 12 cm).

The sample is introduced with a purge stream of helium (5 liters/min) and then irradiated with a 200-W mercury-vapor lamp (vertically mounted in the center of the photolysis coil on Teflon towers). The effluent from the photolysis  
5 coil is directed to a series of cold traps, where liquid and gaseous fractions less volatile than nitric oxide (such as nitrite and nitrate) are removed. Nitric oxide is then carried by the helium stream into the chemiluminescence spectrometer, in which free nitric oxide is detected by  
10 reaction with ozone. Signals are recorded on a digital integrator (model 3393A, Hewlett-Packard). Flow rates and illumination levels in the photolysis cell were designed to result in complete photolysis of the S-N bond of S-nitrosothiols, as confirmed by analysis of effluent from  
15 the cell according to the method of Saville (Saville, B., *Analyst* 83:670-672 (1958)).

To determine what fraction of the total nitric oxide detected in samples was derived from S-nitrosothiols, several control measurements were performed. Mercuric ion  
20 was used to displace nitric oxide selectively from the S-nitrosothiols (Saville, B., *Analyst* 83:670-672 (1958)). Comparison of measured nitric oxide concentrations from samples alternatively pretreated or not pretreated with  $\text{HgCl}_2$  ensured that nitric oxide obtained by photolysis was  
25 derived specifically from S-nitrosothiols. Similarly, as an added measure of confirmation, we distinguished between S-nitrosothiols and free nitric oxide by comparing nitric oxide concentrations in samples alternatively exposed or not exposed to photolyzing illumination.

30 *Methods for Spectrophotometric Experiments and Nitrosylhemoglobin Formation, Examples 14-20*

Purified human  $\text{HbA}_0$  was obtained from Apex Biosciences (Antonini, E. and Brunori, M. *In Hemoglobin and Myoglobin in Their Reactions with Ligands*, American Elsevier

Publishing Co., Inc., New York (1971)). The spectrophotometer used was a Perkin Elmer UV/vis Spectrometer Lambda 2S. All measurements were made at 23°C in a sealed quartz cuvette to which all additions were  
5 made. Deoxygenation was achieved by argon passage through a Hb solution within a sealed quartz cuvette. The degree of deoxygenation can be measured by UV/vis spectrum. Nitrosylation of hemes is achieved by addition of purified NO gas to deoxyHb and the products quantitated by the  
10 extinction coefficient per Antonini and Brunori, *supra*.

#### Example 1: Interactions of NO and RSNO with Hb

It was observed that naturally occurring N-oxides, such as NO and RSNOs (Gaston, B., *et al.*, *Proc. Natl. Acad. Sci. USA* 90:10957-10961 (1993); Scharfstein, J.S., *et al.*,  
15 *J. Clin. Invest.*, 94:1432-1439 (1994); Clancy, R.M., *et al.*, *Proc. Natl. Acad. Sci. USA* 91:3680-3684 (1994)), differed markedly in their reactions with Hb. NO bound very rapidly to deoxyHb (Hb[FeII]), forming relatively stable Hb[FeII]NO complexes (Figure 1A), and converted  
20 oxyHb (Hb[FeII]O<sub>2</sub>) to methemoglobin (Hb[FeIII]) and nitrate (Figure 1B), confirming previous reports (Olson, J.S., *Methods in Enzymol.* 76:631-651 (1981); Toothill, C., *Brit. J. Anaesthy.* 39:405-412 (1967)). In contrast, RSNOs were found to participate in transnitrosation reactions with  
25 sulfhydryl groups of Hb, forming S-nitrosohemoglobin (SNO-Hb), and did not react with the heme centers of either deoxyHb or Hb(FeII)O<sub>2</sub> (Figures 1C and 1D).

#### A. Interaction of NO with deoxyHb

Conversion of deoxyHb (Hb[FeII]) to Hb(FeII)NO is  
30 observed upon incubation of Hb(FeII) with increasing concentrations of nitric oxide. See Figure 1A. a. Deoxy Hb. b, c, d. Reaction mixtures of NO and Hb(FeII) in ratios of 1:1, 2:1 and 10:1, respectively. The reaction product

Hb(FeII)NO formed essentially instantaneously on addition of NO (*i.e.* within instrument dead time).

B. Interaction of NO with oxyHb

Conversion of oxyHb ( $\text{Hb}[\text{Fe}[\text{II}]\text{O}_2$ ) to metHb ( $\text{HbFe}[\text{III}]$ ) is observed upon incubation of oxyHb with increasing concentrations of NO. See Figure 1B. a. oxy Hb. b, c, d. Reaction mixtures containing NO and oxyHb in ratios of 1:1, 2:1 and 10:1, respectively. Methemoglobin formation occurred instantaneously on addition of NO (*i.e.* within instrument dead time).

C. Interaction of S-nitrosothiols with deoxyHb

Conversion of Hb(FeII) to SNO-Hb(FeII) is observed upon incubation of either GSNO (shown) or S-nitrosocysteine (CYSNO) with deoxy Hb. There is little (if any) interaction of RSNO with the heme functionalities of Hb. See Figure 1C. a. deoxyHb. b, c, d. Reaction mixtures of GSNO and Hb(FeII) in ratios of 1:1, 2:1 and 10:1, respectively. Spectra were taken after 60 min of incubation in b, c, and 15 min in d. Further analysis of reaction products revealed the formation of moderate amounts of SNO-Hb in all cases. Yields of SNO-Hb (S-NO/Hb) in b, c, and d at 60 min were 2.5%, 5% and 18.5%, respectively. (See Figure 1D and Figure 2A.)

D. Interaction of S-nitrosothiols with oxyHb

Conversion of  $\text{Hb}(\text{FeII})\text{O}_2$  to SNO-Hb(FeII) $\text{O}_2$  is observed upon incubation of either GSNO (shown) or CYSNO with oxyHb. There is little (if any) reaction of GSNO (or CYSNO) at the heme centers of  $\text{Hb}(\text{FeII})\text{O}_2$ . Specifically, the capacity for  $\text{O}_2$  binding to heme is unaffected by RSNOs. See Figure 1D. a. oxyHb. b, c, d. Reaction mixtures of GSNO and oxyHb in ratios of 1:1, 2:1, and 10:1, respectively. Spectra were taken after 60 min of incubation in the spectrophotometer.

Further analysis of reaction products revealed the formation of SNO-Hb in all cases. Yields of SNO-Hb in spectra *b*, *c* and *d* were 5%, 10% and 50% (S-NO/Hb), respectively. In 5 other determinations, the yield of S-NO/Hb was  $0.37 \pm 0.06$  using GSNO (pH 7.4, 10-fold excess over Hb) and  $\sim 2$  SNO/tetramer ( $1.97 \pm 0.06$ ) using CYSNO (*vida infra*). These last data are in agreement with reports that human HbA contains 2 titratable SH groups.

### Methods

10 Human HbA<sub>0</sub> was purified from red cells as previously described (Kilbourn, R.G., et al., *Biochem. Biophys. Res. Comm.*, 199:155-162 (1994)). Nitric oxide solutions were rigorously degassed and purified according to standard procedure (Beckman, J. S., et al., *Methods in Nitric Oxide*  
15 *Research*, Feelisch and Stamler, eds., Wiley Chichester, U.K. (1996)) and saturated solutions were transferred in air tight syringes. Deoxygenation of Hb was achieved by addition of excess dithionite (NO studies) or by reduction of Hb(FeII)O<sub>2</sub> through evacuation in Thunberg tubes (RSNO  
20 studies; as RSNOs react with dithionite). RSNOs were synthesized as previously described (Gaston, B., et al., (1993); Arnette, D.R. and Stamler, J.S., *Arch. Biochem. Biophys.* 318:270-285 (1995)) Incubations with HbA<sub>0</sub> were made in phosphate buffer, pH 7.4, 0.5 mM EDTA.  
25 Quantifications of SNO-Hb were made according to the method of Saville (Gaston, B., et al., (1993); Stamler, J.S., et al., *Proc. Natl Acad. Sci. USA*, 90:444-448 (1992)) after purification of protein with Sephadex G-25 columns. The Saville method, which assays free NO<sub>x</sub> in solution, involves  
30 a diazotization reaction with sulfanilamide and subsequent coupling with the chromophore N-(naphthyl)ethylenediamine. No low molecular weight S-NO complexes survived this purification and all activity was protein precipitable.

The reactions and spectra were carried out using a Perkin Elmer UV/Vis Spectrometer, Lambda 2S.

Example 2: Allosteric Function of O<sub>2</sub> in Regulation of Hb S-nitrosylation

5       Oxygenation of Hb is associated with conformational changes that increase the reactivity of cys $\beta$ 93 to alkylating reagents (Garel, C., et al., *J. Biochem.*, 123:513-519 (1982); Jocelyn, P.C., *Biochemistry of the SH Group*, Academic Press, London, p.243 (1972); Craescu, C.T.,  
10 et al., *J. Biol. Chem.*, 261:14710-14716 (1986)). The physiological importance of this effect has not been explained previously. It was observed here that rates of S-nitrosation of Hb were markedly dependent on conformational state. In the oxy conformation (R state),  
15 S-nitrosation was more rapid than in the deoxy conformation (T state) (Figure 2A). The rate of S-nitrosation was accelerated in both conformations by alkaline conditions (i.e., rate at pH 9.2 > pH 7.4), which tends to expose the cys $\beta$ 93 that is otherwise screened from reaction by the C-terminal histidine 146 $\beta$ . The salt bridge (asp  $\beta$ 94 --- his  $\beta$ 146) tying down the histidine residue is loosened at high pH. These data suggest that the increase in thiol  
20 reactivity associated with the R state derives, at least in part, from improved NO access rather than a conformation-induced change in pK.  
25

A. Oxygenation accelerates S-nitrosylation of Hb.

Rates of Hb S-nitrosation by S-nitrosocysteine (CYSNO) are faster in the oxy conformation (Hb[FeII]O<sub>2</sub>) than in the deoxy state (Hb[FeII]).

30 Methods

Incubations were performed using 10-fold excess CYSNO over protein (50  $\mu$ M) in aerated 2% borate, 0.5 mM EDTA

(oxyHb), or in a tonometer after rapid O<sub>2</sub> evacuation (deoxyHb). At times shown in Figure 2A, samples were rapidly desalted across G-25 columns (preequilibrated with phosphate buffered saline, 0.5 mM EDTA, pH 7.4) to remove  
5 CYSNO, and analyzed for SNO-Hb by the method of Saville (Stamler, J.S., et al., *Proc. Natl. Acad. Sci. USA*, 89:444-448 (1992)).

B. Deoxygenation accelerates denitrosylation of Hb

Rates of RSNO decomposition (and transfer) are much  
10 faster in the deoxy conformation [SNO-Hb(FeII)] than in the oxy state [SNO-Hb(FeII)O<sub>2</sub>]. The decomposition of SNO-Hb(FeII) is further accelerated by the presence of excess glutathione. Within the dead time of measurements according to this method (~15 seconds), a major fraction of  
15 SNO-Hb(FeII) was converted to GSNO.

Methods

Hbs in PBS (0.5 mM EDTA, pH 7.4) were incubated in air (oxy) or in a tonometer previously evacuated of O<sub>2</sub> (deoxy). SNO-Hb(FeII)O<sub>2</sub> decomposition was determined by the method  
20 of Saville (Saville, B., *Analyst* 83:670-672 (1958)). Spontaneous decomposition of SNO-Hb(FeII) was followed spectrophotometrically by formation of Hb(FeII)NO. Transnitrosation reactions with glutathione were performed by addition of 100-fold excess glutathione over protein (50  
25  $\mu$ M), immediate processing of the reaction mixture under anaerobic conditions followed by rapid TCA precipitation, and analysis of RSNO in the supernatant. Rates of NO group transfer were too rapid to measure accurately by the standard methods used in this study.

Example 3: NO-related Interactions with Cysteine Residues of Hb in Physiological Systems

Given that Hb is largely contained within red blood cells, potential mechanisms by which S-nitrosation of intracellular protein might occur were explored. Incubation of oxygenated rat red blood cells with S-nitrosocysteine resulted in very rapid formation of intracellular SNO-Hb(FeII)O<sub>2</sub> (Figure 3A). Rapid oxidation of Hb was not observed under these conditions. Intraerythrocytic SNO-Hb also formed when red blood cells were treated with S-nitrosohomocysteine or S-nitrosocysteinyglycine, but not with S-nitrosoglutathione (GSNO). Thus, erythrocyte access of RSNOs is thiol group specific. Exposure of oxygenated red blood cells to NO resulted primarily in metHb formation.

Endothelium-derived relaxing factor (EDRF) and hemoglobin

Hb-mediated inhibition of endothelium-dependent relaxations is commonly used as a marker of NO responses. Inasmuch as reactions with either metal or thiol centers of Hb should lead to attenuated NO/EDRF (endothelium-derived relaxing factor) responses, experiments were performed to elucidate the molecular basis of inhibition. Hb preparations in which  $\beta$ 93 thiol groups had been blocked with N-ethylmaleimide (NEM) or the hemes blocked by cyanmet (FeIIICN)-derivitization were studied in an aortic ring bioassay, and their activities were compared with that of native Hb. Both cyanmet-Hb and NEM-Hb caused increases in vessel tone and attenuated acetylcholine (EDRF)-mediated relaxations (Figure 3B). However, native Hb was significantly more effective than either of the modified Hb preparations (Figure 3B). Taken in aggregate, these studies suggest that both the thiol and metal groups of Hb contribute to its NO-related activity. To verify formation of an S-nitrosothiol in Hb, a bioassay was used in which 2

cm segments of thoracic aorta were interposed in Tygon tubing, through which 3 cc of Krebs solution containing Hb (4  $\mu$ M) and ACh (2  $\mu$ M) were circulated by roller pump (1.5 cc/min x 5 min). Analysis of the effluent (Gaston, B., et al., (1993)) revealed the formation of SNO-Hb ( $20 \pm 4$  nM) in 5 of 5 experiments.

#### A. S-nitrosation of intraerythrocytic Hb

Incubation of rat erythrocytes with S-nitrosocysteine (equimolar to heme (5 mM); phosphate buffer pH 7.4, 25°C) leads to rapid formation of intracellular SNO-Hb(FeII)O<sub>2</sub>. MetHb does not form rapidly. Separation of intracellular RSNOs across G-25 columns reveals that only a small percentage exists as low molecular weight S-nitrosothiol (e.g. GSNO) at most time points. By 60 min, 3 of the 4 available SH groups of Hb were S-nitrosated (note that rat Hb contains 4 reactive SH groups). See Figure 3A. Inset shows spectra of SNO-Hb isolated from rat erythrocytes and related analyses. Spectrum A is that of SNO-Hb isolated from erythrocytes following G-25 chromatography. Treatment of A with dithionite results in reduction of the S-NO moiety, liberating free NO which is autocaptured by deoxy Hb, forming Hb(FeII)NO (note that dithionite simultaneously deoxygenates Hb) (spectrum C). This spectrum (C) reveals a stoichiometry of ~3 S-NOs per tetramer. The spectrum of Hb(FeII)NO containing 4 NO's per tetramer is shown for comparison (inset, spectrum B).

#### Methods

At shown intervals, red blood cells were pelleted rapidly by centrifugation, washed three times, lysed in deionized water at 4°C, and the cytosolic fraction subjected to rapid desalting across G-25 columns. Intracellular SNO-Hb was measured by the method of Saville (Gaston, B., et al., (1992); Stamler, J.S., et al., *Proc.*

*Natl. Acad. Sci. USA*, 89:444-448 (1992)), and confirmed spectroscopically (inset of Figure 3A) as described above.

B. Molecular Basis of EDRF/Hb Interaction.

The effects of native Hb on EDRF responses were compared with Hb preparations in which the thiol or heme centers had been blocked by alkylation or cyanmet derivitization, respectively. All preparations of Hb elicited contractions; however, those of native Hb (in which both SH and metal centers are free for interaction) were most pronounced. See Figure 3B. Likewise, acetylcholine (ACh) mediated relaxations were most effectively inhibited by native Hb. Relaxations were inhibited to lesser degrees by cyanmet Hb (CN-Hb) (in which hemes were blocked from reaction) and NEM-Hb (in which thiol groups were alkylated by N-ethylmaleimide). See Table 1. These data illustrate that both heme and  $\beta 93$ SH groups of Hb contribute to reversal of EDRF responses. Direct measurement of SNO-Hb, formed from EDRF under similar conditions, is described in Example 8.

20 Methods

Descending rabbit thoracic aorta were cut into 3 mm rings and mounted on stirrups attached to force transducers (model FT03, Grass Instruments, Quincy, MA) for measurement of isometric tone. The details of this bioassay system have been previously described (Stamler, J.S., et al., *Proc. Natl. Acad. Sci. USA*, 89:444-448 (1992)). Cyanmet Hb was prepared from human HbA according to published protocols (Kilbourn, R.G. et al. *Biochem. Biophys. Res. Comm.*, 199:155-162, (1994)). Alkylation of HbA with N-ethylmaleimide was followed by desalting across G-25 Sephadex to remove excess NEM. Removal of unmodified Hbcys $\beta 93$  was achieved by passage through Hg-containing

affinity columns. The alkylation of free SH groups was verified using 5,5'-dithio-bis[2-nitrobenzoic acid].

TABLE 1

ADDITIONS	% INCREASE IN TENSION	% ACh RELAXATION

Example 4: Transduction of SNO-Hb Vasoactivity

Arterial red blood cells contain two physiologically important forms of hemoglobin: Hb(FeII)O<sub>2</sub> and Hb(FeIII) (Antonini, E. and Brunori, M. *In Hemoglobin and Myoglobin in Their Reactions with Ligands*, American Elsevier Publishing Co., Inc., New York, pp. 29-31 (1971)).

Arterial-venous differences in the S-nitrosothiol content of intraerythrocytic Hb suggest that the NO group is released during red cell transit. Such findings raise the possibility of functional consequences, perhaps influenced by the redox state of heme and its occupation by ligand. SNO-Hb(FeII)O<sub>2</sub> was found to possess modest NO-like activity when tested in a vascular ring bioassay. Specifically, the contraction elicited by SNO-Hb(FeII)O<sub>2</sub> was less than that of native Hb(FeII)O<sub>2</sub>, indicating that S-nitrosation partially reverses the contractile effects of Hb (Figure 4A). By comparison, SNO-Hb(FeIII) was found to be a vasodilator (Figure 4A). Notably, free NO was devoid of relaxant activity in the presence of Hb(FeII)O<sub>2</sub> or Hb(FeIII).

Red blood cells contain millimolar concentrations of glutathione. As equilibria among RSNOs are rapidly established through RSNO/thiol exchange (Arnette, D.R. and Stamler, J.S., *Arch. Biochem. Biophys.*, 318:279-285 (1995)), the vasoactivity of SNO-Hb was reassessed in the presence of glutathione. Figure 4B illustrates that glutathione potentiated the vasodilator activity of both SNO-Hb(FeII)O<sub>2</sub> and SNO-Hb(FeIII). GSNO formation under these conditions (confirmed chemically and in bioassay experiments) appeared to fully account for this effect. Further kinetic analyses revealed that transnitrosation involving glutathione was more strongly favored in the equilibrium with SNO-Hb(FeIII) than SNO-Hb(FeII)O<sub>2</sub> (Figure 4C). Given the findings of steady-state levels of SNO-Hb in red blood cells (Table 2 and Figure 3A), these results suggest that 1) the

equilibrium between naturally occurring RSNOs and Hb(cys $\beta$ 93) lies toward SNO-Hb under physiological conditions; 2) that transnitrosation reactions involving SNO-Hb and GSH are likely to occur within red blood cells  
5 (in these studies, low molecular weight RSNOs have been found in erythrocytes loaded with SNO-Hb); and 3) that oxidation of the metal center of Hb shift the equilibrium toward GSNO, thereby potentially influencing bioactivity.

Additional mechanisms of NO group release from SNO-Hb  
10 were sought. Arterial-venous differences in levels of SNO-Hb raised the possibility that S-NO bond stability may be regulated by the changes in Hb conformation accompanying deoxygenation. To test this possibility, the rates of NO group release from SNO-Hb(FeII)O<sub>2</sub> and SNO-Hb(FeIII) were  
15 compared. Deoxygenation was found to enhance the rate of SNO-Hb decomposition (Figure 2B). These rates were accelerated greatly by glutathione in a reaction yielding GSNO (Figure 2B). The results illustrate that O<sub>2</sub>-metal interactions influence S-NO affinity, and suggest a new  
20 allosteric function for Hb.

For SNO-Hb to be of physiological importance it must transduce its NO-related activity across the erythrocyte membrane. This possibility was explored by incubating erythrocytes containing SNO-Hb in physiologic buffer, and  
25 measuring the accumulation of extracellular RSNOs over time. Figure 4D illustrates that red blood cells export low molecular weight (trichloroacetic acid precipitable) S-nitrosothiols under these conditions. Importantly, the degree of hemolysis in these experiments was trivial  
30 (<0.5%), and correction for lysis did not significantly impact on rates of RSNOS release. These results establish that an equilibrium exists between low molecular weight and protein RSNOs within the red cell, and that intracellular location is unlikely to be a limiting factor in the

transduction of such NO-related activity to the vessel wall.

A. Concentration-effect responses of different SNO-Hb preparations

5        Contractile effects of  $\text{Hb(FeII)O}_2(\blacktriangle)$  are shown to be partially reversed by S-nitrosation ( $\text{SNO-Hb[FeII]O}_2(\blacksquare)$ ;  $P = 0.02$  by ANOVA vs  $\text{Hb(FeII)O}_2$ ) (See Figure 4A.). Oxidation of the metal center of SNO-Hb ( $\text{SNO-Hb[FeIII]}(\bullet)$ ) converts the protein into a vasodilator ( $P < 0.0001$  by ANOVA vs.

10  $\text{SNO-Hb[FeII]O}_2$ ), with potency comparable to that of other S-nitrosoproteins (Stamler, J.S., et al., *Proc. Natl. Acad. Sci. USA*, 89:444-448 (1992)). The contractile properties of  $\text{Hb(FeIII)}$  are shown for comparison ( $\square$ );  $n = 6-17$  for each data point.

15 Methods

Details of the vessel ring bioassay have been published (Stamler, J.S., et al., *Proc. Natl. Acad. Sci. USA* 89:444-448 (1992)). SNO-Hb( $\text{FeII}$ ) $\text{O}_2$  preparations were synthesized with 10-fold excess S-nitrosocysteine (CYSNO)

20 over  $\text{Hb(FeII)O}_2$  protein (2% borate, 0.5 mM EDTA, ~15 min incubation), after which desalting was performed across Sephadex G-25 columns. CYSNO was synthesized in 0.5 N HCl, 0.5 mM EDTA and then neutralized (1:1) in 1 M phosphate buffer containing 0.5 mM EDTA. SNO-Hb( $\text{FeIII}$ ) preparations

25 followed a similar protocol, but used  $\text{Hb(FeIII)}$  as starting material. The latter was synthesized by treatment of  $\text{Hb(FeII)O}_2$  with excess ferricyanide, followed by desalting across G-25 columns. SNO-Hb concentrations were verified spectroscopically and the S-nitrosothiol content was

30 determined by the method of Saville (Stamler, J.S., et al., *Proc. Nat. Acad. Sci USA* 89:444-448 (1992)). The S-NO/tetramer stoichiometry for both SNO-Hb preparations was

~2. Oxidation of the heme was undetectable by uv-spectrophotometric methods.

B. Potentialiation of SNO-Hb effects by glutathione

Addition of glutathione (100  $\mu$ M) to bioassay chambers  
5 potentiates the dose-response to both SNO-Hb(FeII)O<sub>2</sub> (■) and  
SNO-Hb(FeIII) (●) (See Figure 4B. n = 6-12; p < 0.0001 for  
both by ANOVA, compared with the respective tracings in  
Figure 4A. Glutathione had a transient affect on baseline  
tone in some experiments, and did not significantly  
10 influence the response to Hb(FeII)O<sub>2</sub> (▲).

C. Transnitrosation between SNO-Hb and glutathione

Rates of NO group transfer from SNO-Hb (100  $\mu$ M) to  
glutathione (10 mM) are displayed for SNO-Hb(FeII)O<sub>2</sub> (oxy)  
and SNO-Hb(FeIII) (met) (n=5). Data are presented as the  
15 amount of GSNO formed relative to the starting SNO-Hb  
concentration. The transfer is more rapid for SNO-  
Hb(FeIII) than SNO-Hb(FeII)O<sub>2</sub> (p<0.002 by ANOVA),  
suggesting that the GSNO/SNO-Hb equilibrium is shifted  
toward GSNO by formation of methHb.

20 Methods

Thiol/SNO-Hb exchange, forming GSNO, was verified  
chemically (Stamler, J.S., et al., *Proc. Natl Acad. Sci.*  
*USA*, 89:444-448 (1992)) following trichloroacetic acid  
precipitation (n=5). These results were verified in  
25 separate experiments by measuring the residual SNO-Hb  
concentration, following separation of reaction mixtures  
across G-25 columns.

D. Export of S-nitrosothiols by red blood cells

Human red blood cells containing SNO-Hb are shown to  
30 export low molecular weight RSNOs over time. Hemolysis,  
which ranged from 0-<0.5% over one hour and did not

correlate with rates of RSNO release, could account for only a trivial fraction of the measured extracellular RSNO.

### Methods

Packed human red blood cells were obtained by  
5 centrifugation, washed, and resuspended in phosphate  
buffered saline containing 5 mM SNOCYS (0.5 mM EDTA, pH  
7.4) for one hour. This results in a red cell preparation  
containing SNO-Hb (FeII $O_2$ /FeIII mixture) with a  
stoichiometry of 0.5 S-NO/tetramer. The red blood cells  
10 were then washed repeatedly to remove residual CYSNO  
(verified), and incubated in Krebs' solution (1:4). The  
accumulation of extracellular RSNO was measured over time  
by the method of Saville (Saville, B., *Analyst*, 83:670-672  
(1958)). Hemolysis was determined by spectral analysis of  
15 red blood cell supernatants following centrifugation.

### Example 5: SNO-Hb Bioactivity In Vivo

Systemic administration of cell-free Hb results in  
hypertensive responses which have been attributed to NO  
scavenging by the heme (Vogel, W.M., et al., *Am. J.*  
20 *Physiol.* 251:H413-H420 (1986); Olsen, S.B., et al.,  
*Circulation* 93:329-332 (1996)). To determine if SNO-Hb is  
free of this adverse affect, and to explore if *in vitro*  
mechanisms of NO release extend to the *in vivo*  
circumstance, we compared responses to Hb and SNO-Hb  
25 infused as a bolus into the femoral vein of anesthetized  
rats. As illustrated in Figure 5, Hb(FeII) $O_2$  (200 nmol/kg)  
caused an increase in mean arterial pressure of  $20 \pm 3$  mm  
Hg ( $n = 4$ ;  $P < 0.05$ ). In contrast, SNO-Hb(FeII) $O_2$  did not  
exhibit hypertensive effects and SNO-Hb(FeIII) elicited  
30 hypotensive responses (Figure 5). Thus, the profiles of  
these compounds *in vivo* closely resemble those seen *in*  
*vitro* (Figure 4A). Moreover, to demonstrate that the  
physiological responses of red cells are comparable to

those of cell-free Hb preparations, erythrocytes containing SNO-Hb were injected into the femoral vein of rats pretreated with L-NMMA (50 mg/kg) to deplete endogenous RSNOs. At levels of SNO-Hb comparable to those found in  
5 the normal rat (0.1-0.5  $\mu$ M), SNO-Hb containing red blood cells elicited hypotensive responses ( $8 \pm 1$  mm Hg; mean  $\pm$  SEM; n=9), whereas native (SNO-Hb depleted) red blood cells did not (P=0.001). These changes in mean blood pressure of ~10% are on the order of those that differentiate  
10 normotension from hypertension in man, and in the therapeutic range of some antihypertensive regimens. The effects of both Hb and SNO-Hb -- whether cell-free or contained within red cells -- were transient, suggesting that S-nitrosylation of Hb and metabolism of SNO-Hb is  
15 occurring *in vivo*, with consequent restoration of blood pressure. The bioactivity of SNO-Hb in blood, where S-NO/heme stoichiometries approach 1:50,000, is a dramatic illustration of the resistance of this NO-related activity to Hb(Fe) inactivation.

20 *In vivo* effects of cell-free Hb and SNO-Hbs

Administration of 2-200 nmol/kg Hb(FeII)O<sub>2</sub> (as a bolus) into the femoral vein of a Sprague-Dawley rat is shown to increase mean arterial pressure in a dose-dependent manner. At 200 nmol/kg, mean arterial pressure  
25 increased by 25 mm Hg ( $20 \pm 3$  mm Hg; n = 4; P < 0.05). Elevations in blood pressure reversed within 10-15 minutes. SNO-Hb(FeII)O<sub>2</sub> infusions (over the same dose range) are shown to ameliorate Hb(FeII)O<sub>2</sub>-induced hypertension without causing overt changes in blood pressure. A similar  
30 response was seen at higher doses. By comparison, SNO-Hb(FeIII) infusions caused a significant fall in mean arterial pressure (pre  $108 \pm 4$  mm Hg; post  $74 \pm 6$  mm Hg, n=5; P < 0.05) at the highest dose (200 nmol/kg). Hypotensive responses tended to be transient with blood

pressure normalizing over 10 minutes. A fall in blood pressure was also seen with injection of erythrocytes containing SNO-Hb.

## 5 Methods

Rats were anesthetized by intraperitoneal injection of pentobarbital and the femoral arteries and veins accessed by local cut down. The artery was then cannulated and the blood pressure monitored continuously using a Viggo Spectramed pressure transducer attached to a Gould recorder. An IBM PC (DATA Q Cudas) was used for data acquisition.

### Example 6: Loading of Red Blood Cells With S-Nitrosothiols

Incubation of rat erythrocytes with S-nitrosocysteine (equimolar to heme (5 mM); phosphate buffer pH 7.4, 25°C) leads to rapid formation of intracellular S-nitrosothiols. MetHb does not form rapidly. Separation of cell content across G-25 columns establishes the formation of intraerythrocytic low molecular weight S-nitrosothiol, e.g. S-nitrosogluthathione, (GSNO). By 2 minutes, one can achieve as much as millimolar GSNO.

### Method for assay of RSNO

S-nitrosocysteine (5 mM) treated red blood cells are pelleted rapidly by centrifugation, washed three times, lysed in deionized water at 4°C, and the cytosolic fraction subjected to rapid desalting across G-25 columns. Intracellular RSNO is measured by the method of Saville and can be confirmed spectroscopically.

### Effects on blood pressure from loaded red blood cells

Red blood cells treated with S-nitrosocysteine (to produce SNO-RBCs) and introduced into the femoral vein of a Sprague-Dawley rat decreased mean arterial pressure in a

dose-dependent manner. For red blood cells in which SNO-Hb was assayed at 0.3  $\mu$ M (the endogenous in vivo SNO-Hb concentration), arterial pressure decreased by  $8 \pm 1$  mm Hg (mean  $\pm$  SEM for 9 experiments;  $p < 0.001$  compared to untreated red blood cell controls). For red blood cells in which SNO-Hb was assayed at 0.5  $\mu$ M, arterial pressure decreased by 10 mm Hg. For red blood cells in which SNO-Hb was assayed at 0.1  $\mu$ M (a sub-endogenous SNO-Hb concentration), arterial pressure decreased by 6 mm Hg. The administration of untreated red blood cells caused no effect or a slight increase in arterial blood pressure. Administration of L-monomethyl-L-arginine (L-NMMA; 50 mg/kg) caused an increase in blood pressure of about 20 mm Hg. Changes in blood pressure from a bolus administration of loaded red blood cells lasted 15-20 minutes.

#### Further methods

Rats were anesthetized by intraperitoneal injection of pentobarbital and the femoral arteries and veins accessed by local cut down. The artery was then cannulated and the blood pressure monitored continuously using a Viggo Spectramed pressure transducer attached to a Gould recorder. An IBM PC (DATA Q Codas) was used for data acquisition.

#### Example 7: Effects of SNO-Hb on Coronary Vasodilation, Coronary Flow and Blood Pressure

SNO-Hb was synthesized as described in Example 4A. Completion of the reaction was determined as described in Example 4A. Twenty-four healthy mongrel dogs (25-30 kg) were anesthetized with intravenous thiamylal sodium (60-80 mg/kg) and subjected to left thoracotomy in the fourth intercostal space. The left circumflex coronary artery distal to the left atrial appendage was minimally dissected. A pair of 7-MHz piezoelectric crystals (1.5 X

2.5 mm, 15-20 mg) was attached to a Dacron backing and sutured to the adventitia on opposite surfaces of the dissected vessel segment with 6-0 prolene. Oscilloscope monitoring and on-line sonomicrometry (sonomicrometer 120-  
5 2, Triton Technology, San Diego, CA) were used to ensure proper crystal position. A pulse Doppler flow probe (10 MHz, cuff type) was implanted distal to the crystals. An inflatable balloon occluder was also placed distal to the flow probe. All branches of the circumflex artery between  
10 the crystals and the occluder were ligated. Heparin sodium-filled polyvinyl catheters were inserted into the left ventricular cavity via the apex, into the left atrium via the atrial appendage, and into the ascending aorta via the left internal thoracic artery. The catheters, tubing,  
15 and wires were tunnelled to a subcutaneous pouch at the base of the neck.

After a 10 to 15 day recovery period, the catheters and wires were exteriorized under general anesthesia, and 2-3 days later, each dog was given a bolus injection of  
20 SNO-Hb (0.4 mg) to evaluate vascular response. Two dogs that demonstrated <5% dilation of epicardial coronary vessels were excluded from subsequent studies, and two were excluded because of other technical reasons.

Dogs were trained and studied while loosely restrained  
25 and lying awake in the lateral recumbent position. The laboratory was kept dimly illuminated and quiet. Aortic pressure, left ventricular end-diastolic pressure  $dp/dt$  external coronary diameter and coronary flow were monitored continuously. In 10 dogs, 0.1 ml of SNO-Hb solution, 50  
30 nM/kg, was injected via the left atrial catheter. To verify potential effects of solvent on vasculature, 0.1 ml injections of 30% ethanol in distilled water were given as vehicle control. Between injections, phasic coronary blood flow and coronary artery diameter were allowed to return to  
35 preinjection levels (minimum 15 minutes). Allowing a 15

minute period between injections resulted in no modification of repeated doses injections. To assess the direct and potential flow mediated indirect vasodilation effects of SNO-Hb on the conductance vessels, the dose was  
5 repeated in 6 of 10 dogs with partial inflation of the adjustable occluder to maintain coronary blood flow at or slightly below preinjection levels. The response to acetylcholine chloride (Sigma Chemical) was assessed in another group of 10 dogs following a similar protocol to  
10 that used for SNO-Hb.

Epicardial coronary diameter, coronary blood flow, heart rate, and aortic and left ventricular end-diagnostic pressures were compared before and after each SNO-Hb injection. The maximum changes in coronary dimension and  
15 blood flow were expressed as a function of increasing doses of SNO-Hb. The response of coronary dimension to increasing doses followed a characteristic sigmoid dose-response curve that could be described by the following equation

$$Effect = \frac{maximal\ effect\ x\ dose}{K_D + dose}$$

20 where  $K_D$  is the drug-receptor complex dissociation constant and is the dose at which 50% of the maximum response ( $EC_{50}$ ) is achieved. In each animal, a nonlinear least-squares regression ( $r^2 > 0.90$ ) was performed on the dose-response data. The regression was constrained to the above  
25 equation. From the regression, values for maximum response and  $K_D$  were obtained for each individual animal. The mean of these values was then calculated to obtain an average  $K_D$  and maximum response for the study group. These values were used to generate a mean curve, which was plotted with  
30 the mean dose-response values. (See Figures 6A-6F.)

Example 8: Endogenous Levels of S-nitrosohemoglobin and Nitrosyl(FeII)-Hemoglobin in Blood

To determine if SNO-Hb is naturally occurring in the blood, and if so, its relationship to the O<sub>2</sub> transport capacity and nitrosylated-heme content of red cells, an analytical approach was developed to assay the S-nitrosothiol and nitrosyl-heme content of erythrocytes (Table 2). Arterial blood was obtained from the left ventricle of anesthetized rats by direct puncture and venous blood was obtained from the jugular vein and inferior vena cava. Hb was then purified from red cells and assayed for RSNO and (FeII)NO content. Arterial blood contained significant levels of SNO-Hb, whereas levels were virtually undetectable in venous blood (Table 2).

Measurements made 45 minutes after infusion of the NO synthase inhibitor N<sup>ω</sup>-monomethyl-L-arginine (L-NMMA) (50 mg/kg), showed a depletion of SNO-Hb as well as total Hb-NO (82 and 50 ± 18%, respectively; n = 3-5; p < 0.05). These data establish the endogenous origin of SNO-Hb, although some environmental contribution is not excluded. The arterial-venous distribution seen for SNO-Hb was reversed in the case of Hb(FeII)NO, which was detected in higher concentrations in partially deoxygenated (venous) erythrocytes (Table 2). Accordingly, the proportion of nitrosylated protein thiol and heme appears to depend on the oxygenation state of the blood. Consistent with these findings, Wennmalm and coworkers have shown that Hb(FeII)NO forms mainly in venous (partially deoxygenated) blood (Wennmalm, A., et al., *Br. J. Pharmacol.* 106(3):507-508 (1992)). However, levels of Hb(FeII)NO *in vivo* are typically too low to be detected (by EPR) and SNO-Hb is EPR-silent (*i.e.*, it is not paramagnetic). Thus, photolysis-chemiluminescence represents an important technological advance, as it is the first methodology

capable of making quantitative and functional assessments of NO binding to Hb under normal physiological conditions.

Table 2

Endogenous Levels of S-Nitrosohemoglobin and  
Nitrosyl(FeII)-Hemoglobin in Blood

Site	SNO-Hb (nM)	Hb(FeI)NO (nm)
Arterial	311 ± 55*	536 ± 99 †
Venous	32 ± 14	894 ± 126

\*P < 0.05 vs venous; † P < 0.05 for paired samples vs venous

10 Methods

Blood was obtained from the left ventricle (arterial) and jugular vein (venous) of anesthetized Sprague-Dawley rats. Comparable venous values were obtained in blood from the inferior vena cava. Red blood cells were isolated by centrifugation at 800 g, washed three times in phosphate buffered saline at 4°C, lysed by the addition of 4-fold excess volume of deionized water containing 0.5 mM EDTA, and desalted rapidly across G-25 columns according to the method of Penefsky at 4°C. In 24 rats, Hb samples were divided in two aliquots which were then treated or not treated with 10-fold excess HgCl<sub>2</sub> over protein concentration as measured by the method of Bradford. Determinations of SNO-Hb and Hb(FeII)NO were made by photolysis-chemiluminescence. In 12 additional rats, further verification of the presence of SNO-Hb was made by assaying for nitrite after HgCl<sub>2</sub> treatment. Specifically, samples (with and without HgCl<sub>2</sub>) were separated across

Amicon-3 (Centricon filters, m.w. cut off 3,000) at 4°C for 1 h, and the low molecular weight fractions collected in airtight syringes containing 1  $\mu$ M glutathione in 0.5 N HCl. Under these conditions, any nitrite present was converted  
5 to S-nitrosoglutathione, which was then measured by photolysis-chemiluminescence (detection limit ~1 nM). SNO-Hb was present in all arterial samples, and levels determined by this method ( $286 \pm 33$  nM) were virtually identical to and not statistically different from those  
10 shown in Table 2. In venous blood, SNO-Hb was undetectable ( $0.00 \pm 25$  nM); levels were not statistically different from those given above.

#### Method for assay of S-nitrosohemoglobin

A highly sensitive photolysis-chemiluminescence  
15 methodology was employed. A somewhat similar assay has been used for measuring RSNOs (S-nitrosothiols) in biological systems (Gaston, B., et al., *Proc. Natl. Acad. Sci. USA* 90:10957-10961 (1993); Stamler, J.S., et al., *Proc. Natl. Acad. Sci. USA* 89:7675-7677 (1992)). The  
20 method involves photolytic liberation of NO from the thiol, which is then detected in a chemiluminescence spectrometer by reaction with ozone. The same principle of operation can be used to cleave (and measure) NO from nitrosyl-metal compounds (Antonini, E. and Brunori, M. In *Hemoglobin and*  
25 *Myoglobin in Their Reactions with Ligands*, American Elsevier Publishing Co., Inc., New York, pp. 29-31 (1971)). With adjustment of flow rates in the photolysis cell, complete photolysis of the NO ligand of Hb(FeII)NO could be achieved. Standard curves derived from synthetic  
30 preparations of SNO-Hb, Hb(FeII)NO, and S-nitrosoglutathione were linear ( $R > 0.99$ ), virtually superimposable, and revealing of sensitivity limits of approximately 1 nM. Two analytical criteria were then found to reliably distinguish SNO-Hb from Hb(FeII)NO:

1) signals from SNO-Hb were eliminated by pretreatment of samples with 10-fold excess  $\text{HgCl}_2$ , while  $\text{Hb(FeII)NO}$  was resistant to mercury challenge; and 2) treatment of SNO-Hb with  $\text{HgCl}_2$  produced nitrite (by standard Griess reactions) in quantitative yields, whereas similar treatment of  $\text{Hb(FeII)NO}$  did not. UV/VIS spectroscopy confirmed that NO remained attached to heme in the presence of excess  $\text{HgCl}_2$ .

Example 9: Inhibition of Platelet Aggregation by S-Nitrosohemoglobins

Methods to prepare human  $\text{HbA}_0$  were as described in Example 1 "Methods" section. Methods to make SNO- $\text{Hb(FeII)O}_2$  were as described for Example 2A. Methods to make SNO- $\text{Hb(FeIII)}$  were as in Example 1 (see parts B, C, and "Methods" in Example 1). Quantifications of SNO-hemoglobins were made as in Example 1 according to the method of Saville (Saville, B., *Analyst* 83:670-672 (1958)) and by the assay as described in Example 8, "Method for assay of S-nitrosohemoglobin."

Venous blood, anticoagulated with 3.4 nM sodium citrate, was obtained from volunteers who had not consumed acetylsalicylic acid or any other platelet-active agent for at least 10 days. Platelet-rich plasma was prepared by centrifugation at  $150 \times g$  for 10 minutes at  $25^\circ\text{C}$  and was used within 2 hours of collection. Platelet counts were determined with a Coulter counter (model ZM) to be  $1.5$  to  $3 \times 10^8/\text{ml}$ .

Aggregation of platelet-rich plasma was monitored by a standard nephelometric technique in which results have been shown to correlate with bleeding times. Aliquots (0.3 ml) of platelets were incubated at  $37^\circ\text{C}$  and stirred at 1000 rpm in a PAP-4 aggregometer (Biodata, Hatsboro, PA). Hemoglobins were preincubated with platelets for 10 min and aggregations were induced with  $5 \mu\text{M}$  ADP. Aggregations were quantified by measuring the maximal rate and extent of

change of light transmittance and are expressed as a normalized value relative to control aggregations performed in the absence of hemoglobin.

The results of the aggregation assays are shown in  
5 Figures 7A, 7B and 7C. Standard deviations are shown as vertical bars. SNO-Hb[Fe(II)]O<sub>2</sub> causes some inhibition of platelet aggregation at the higher concentrations tested. SNO-Hb[Fe(III)] also inhibits platelet aggregation when present at concentrations of 1 μM and above, but to a much  
10 greater extent than SNO-Hb[Fe(II)]O<sub>2</sub>.

#### Example 10: Effect of SNO-Hbs on cGMP

Platelet rich plasma (PRP) was incubated with either hemoglobin, SNO-oxy Hb, or SNO-metHb for 5 min, after which the assay was terminated by the addition of 0.5 ml of ice  
15 cold trichloroacetic acid to 10%. Ether extractions of the supernatant were performed to remove trichloroacetic acid, and acetylation of samples with acetic anhydride was used to increase the sensitivity of the assay. Measurements of cyclic GMP were performed by radioimmunoassay (Stamler, J.  
20 *et al.*, *Circ. Res.* 65:789-795 (1989)).

Results are shown in Figure 8. For all concentrations of Hb tested (1, 10 and 100 μM), the concentration of cGMP measured for SNO-Hb(FeIII) was less than that of native Hb.

#### Example 11: Polynitrosation of Hb

25 A. HbA<sub>0</sub> (oxy) was incubated with S-nitrosoglutathione at a ratio of 6.25 S-nitrosoglutathione/HbA<sub>0</sub> for 240 minutes at pH 7.4 at 25°C and desalted over Sephadex G-25 columns. Spectra were run in the presence (spectrum B, Figure 9A) and absence (spectrum A, Figure 9A) of dithionite. The  
30 shift in the spectrum is indicative of 2 SNO groups/tetramer.

B. HbA<sub>0</sub> was incubated with 100-fold excess S-nitrosoglutathione over protein for 240 minutes at pH 9.2, followed by desalting over a G-25 column. A portion was then treated with dithionite. The spectra in Figure 9B  
5 indicate that Hb has been nitrosated at multiple sites.

C. HbA<sub>0</sub> was treated with 100-fold excess S-nitroscysteine over tetramer at pH 7.4, 25°C for 5-20 min. After various times of treatment, the protein was desalted over a G-25 column and treated with dithionite. The spectra show  
10 progressive polynitrosation of Hb with time (spectra A to F in Figure 9C). After 5 minutes of treatment with 100-fold excess S-nitrosocysteine, 0.09 NO groups had added per tetramer (spectrum A of Figure 9C); after 20 minutes, at least 4 NO groups had added (spectrum F). At intermediate  
15 time points, 0.4 NO groups (spectrum B), 1.58 NOs (spectrum C), 2.75 NOs (spectrum D) or 2.82 NOs had added per tetramer (spectrum E).

D. Rat Hb was treated with 100x S-nitrosoglutathione excess over tetramer for 3 hours at pH 7.4. The protein  
20 was then desalted by passage through a G-25 column. A portion of the desalted protein was treated with dithionite (spectrum B in Figure 9D; the protein of spectrum A was left untreated by dithionite). Spectrum B in Figure 9D is illustrative of a ratio of 6 RNOs/Hb.

25 E. A time course experiment tracking the extent of nitrosation of HbA<sub>0</sub> with time was performed (Figure 9E). Treatment of HbA<sub>0</sub> was with 10x excess S-nitrosocysteine at pH 7.4, 25°C or with 100x excess S-nitroscysteine under the same conditions. Analysis for SNO and NO was performed by  
30 the method of Saville and by UV spectroscopy as in Jia, L. et al., *Nature* 380:221-226 (1996). Under these conditions

the heme is ultimately oxidized; the rate is time dependent.

Treatment with 10x excess S-nitrosocysteine nitrosylates only the thiol groups of the two reactive  
5 cysteine residues of HbA<sub>0</sub>. Inositol hexaphosphate is known to shift the allosteric equilibrium towards the T-structure (ordinarily, the deoxy form). Treatment with 100x excess nitrosates additional groups; i.e., the product has more than 2 NO groups/tetramer.

10 Example 12: Effect of SNO-Hb(FeII)O<sub>2</sub> on Blood Flow

SNO-Hb(FeII)O<sub>2</sub>, having a SNO/Hb ratio of 2, was prepared (from HbA<sub>0</sub>) by reaction with S-nitrosothiol. Rats breathing 21% O<sub>2</sub> were injected (time 0) with Hbs prepared from HbA<sub>0</sub> as indicated in Figure 10 (open circles, SNO-Hb  
15 (100 nmol/kg); filled circles, SNO-Hb (1000 nmol/kg); filled squares, unmodified Hb (1000 nmol/kg)). Three rats were used per experiment. Blood flow was measured in brain using the H<sub>2</sub> clearance method; microelectrodes were placed in the brain stereotactically. Concomitant PO<sub>2</sub>  
20 measurements revealed tissue PO<sub>2</sub> = 20. Thus, SNO-Hb improves blood flow to the brain under normal physiological conditions, whereas native Hb decreases blood flow. NO group release is promoted by local tissue hypoxia.

25 Example 13: Effects of SNO-Hb(FeII)O<sub>2</sub>, SNO-Hb(FeIII) and (NO)<sub>x</sub>-Hb(FeIII) on Tension of Rabbit Aorta

Hemoglobin was treated with either 1:1, 10:1 or 100:1 S-nitrosocysteine to Hb tetramer for 1 hour, processed as in Example 4. The products of the reactions done with 1:1 and 10:1 excess were assayed by the Saville assay and by  
30 standard spectrophotometric methods. The product of the reaction done at the 1:1 ratio is SNO-Hb(Fe)O<sub>2</sub>; SNO-Hb(FeIII) is found following reaction with 1:10 excess CYSNO/tetramer.

The aortic ring bioassay was performed as described in Example 4. The product of the reaction in which a ratio of 100:1 CYSNO/Hb tetramer was used, contains 2 SNOs as well as NO attached to the heme. The potency of the 100:1  
5 CYSNO/Hb product is much greater than that of SNO-Hb(FeIII) and is indicative of polynitrosation (see Figure 11).

Example 14: Effect of Oxygenation on Partially Nitrosylated Hemoglobin

The effect of oxygenation on partially nitrosylated Hb  
10 was examined by following spectral changes in the Soret region upon the addition of air to partially nitrosylated Hb. Hemoglobin A (17  $\mu$ M) was deoxygenated by bubbling argon through a 1 ml solution in 100 mM phosphate (pH 7.4), for 45 minutes. Nitric oxide was added by injection of 0.5  
15  $\mu$ l of a 2 mM solution, stored under nitrogen. The final heme:NO ratio was 68:1. The solution was slowly aerated by sequential 50  $\mu$ l injections of room air. Figure 12 shows that the initial additions of air failed to produce a true isobestic point, indicating changes in the concentrations  
20 of at least three absorbent species. Later additions of air did produce a true isobestic point, indicative of the conversion of deoxyhemoglobin to oxyhemoglobin, with the loss of nitrosyl heme. The results show that nitrosylated Hb is not a stable end product.

25 Example 15: Conversion of Nitrosylhemoglobin to SNO-Hemoglobin

The hypothesis that the nitric oxide is transferred from the heme iron to a thiol residue, forming nitrosothiol upon oxygenation, was tested. Hemoglobin A (400  $\mu$ M) was  
30 deoxygenated by bubbling argon through a 1 ml solution in 100 mM phosphate (pH 7.4), for 45 minutes. Nitric oxide was added by injection of an appropriate volume of a 2 mM solution, stored under nitrogen, to achieve different NO/Hb

ratios. The solutions were then exposed to air by vigorous vortexing in an open container. Samples were then analyzed by Saville assay and by chemiluminescence after UV photolysis. Data are shown as mean  $\pm$  standard error ( $n > 3$ ). Figure 13 shows that S-nitrosothiol is formed in this manner, and that the efficiency of this reaction is greatest at high ratios of heme to nitric oxide. Amounts are highest at very high NO/Hb ratios, i.e.,  $> 2:1$ . This result implies that nitrosyl Hb entering the lung is converted into SNO-Hb, as under physiological conditions the ratio of heme to NO is high.

#### Example 16: Effects Dependent upon Heme:NO Ratio

It was proposed that the binding of nitric oxide to the heme of the  $\beta$  chain was inherently unstable, and that the reason for lower yields of SNO-Hb at higher concentrations of nitric oxide, was a loss of bound nitric oxide as a result of this instability. Hemoglobin A ( $17.5 \mu\text{M}$ ) was deoxygenated by bubbling argon through a 1 ml solution in 100 mM phosphate (pH 7.4), for 45 minutes. Nitric oxide was added by sequential injections of an appropriate volume of a 2 mM solution, stored under nitrogen. Figure 14A: Difference spectra of the nitric oxide hemoglobin mixture and the starting deoxyhemoglobin spectrum are shown. Figure 14B: The peak wavelength of the difference spectra plotted against the concentration of nitric oxide added to the solution. These data show that addition of small amounts of nitric oxide (heme:NO ratios of approximately 70:1) produce predominantly nitrosylhemoglobin and some oxidized hemoglobin. However, nitric oxide additions of the order of  $10 \mu\text{M}$  result in the formation of oxidized hemoglobin. Heme:NO ratios at this point are approximately 7:1. As the concentration of nitric oxide is increased by further additions of nitric oxide, the predominant species formed becomes

nitrosylhemoglobin (heme:NO ratio 1:1). The results in Figures 14A and 14B show that under anaerobic conditions, the addition of increasing quantities of nitric oxide to Hb results first in the production of nitrosylhemoglobin and then oxidized Hb (metHb). At very high levels of nitric oxide, nitrosyl-hemoglobin is once again seen as the nitric oxide first reduces metHb to deoxyHb (producing nitrite), then binds NO. This drives the conformational change of T-structure Hb to R-structure, stabilizing the  $\beta$  heme-nitric oxide bond. The appearance of oxidized Hb at heme to nitric oxide ratios of approximately 10:1 indicates the decay of the heme/NO bond to produce oxidized Hb and nitric oxide anion (nitroxyl). The presence of nitric oxide anion was confirmed by detection of  $N_2O$  in the gas phase by gas chromatography mass spectrometry and by the production of  $NH_2OH$ .

Example 17: Effects upon Oxygenation of Nitrosyl-deoxyHb

Hemoglobin A (20.0  $\mu M$ ) was deoxygenated by bubbling argon through a 1 ml solution in 100 mM phosphate (pH 7.4), for 45 minutes. In both Figure 15A and Figure 15B, the lowest to the highest spectra indicate the sequential additions of air. These are difference spectra in which the pure deoxyHb spectrum occurs at zero absorbance. The peak at 419 nm is from nitrosylhemoglobin; oxidized hemoglobin absorbs at 405 nm.

In the experiments shown in Figure 15A, hemoglobin was gradually oxygenated by sequential additions of 10  $\mu l$  of room air by Hamilton syringe. Spectra are shown as difference spectra from the initial deoxyhemoglobin spectrum. In the experiments shown in Figure 15B, nitric oxide (1  $\mu M$ ) was added by injection of 0.5  $\mu l$  of a 2 mM solution, stored under nitrogen. Final heme:NO ratio was 80:1. The solution was gradually oxygenated by sequential additions of 10  $\mu l$  of room air. Spectra are shown as

difference spectra from the initial deoxyhemoglobin spectrum. These data show the initial formation of a nitrosylhemoglobin peak, along with some formation of oxidized hemoglobin, which disappears after the addition of approximately 30  $\mu$ l of air. The results indicate that a small quantity of nitrosyl Hb is formed upon addition of low ratios of nitric oxide to deoxy Hb, and that this nitrosyl Hb is lost upon oxygenation.

Example 18: Role of  $\beta$ 93Cys in Destabilizing Nitrosyl-Heme

10        Recombinant hemoglobins were obtained from Clara Fonticelli at the University of Maryland School of Medicine.  $\beta$ 93Ala represents a single amino acid substitution within human hemoglobin A, whilst  $\beta$ 93Cys represents a wild type control. Recombinant hemoglobin (5  $\mu$ M containing either a wild type cysteine ( $\beta$ 93Cys) or a mutant alanine ( $\beta$ 93Ala) at position  $\beta$ 93 was deoxygenated as in Figures 15A and 15B. Nitric oxide (1  $\mu$ M) was added by injection of 0.5  $\mu$ l of a 2 mM solution, stored under nitrogen. The final heme:NO ratio was 20:1. The solution was gradually oxygenated by sequential additions of 10  $\mu$ l of room air. The absorption at 418 nm of difference spectra versus initial deoxyhemoglobin spectra is shown in Figure 16. These data indicate that within the mutant, a nitrosyl adduct was formed that was not lost upon addition of room air. However, the nitrosyl adduct formed within the wild type was lost after addition of greater than 10  $\mu$ l of room air. This shows that NO is not lost from this nitrosyl (FeII) heme in a mutant Hb that does not possess a thiol residue at position  $\beta$ 93. Therefore, this thiol, which is in close proximity to the heme within the R-structure, is critical for destabilizing the heme nitric oxide bond.

Example 19: SNO-Hb from Nitrosyl-Hb Driven by O<sub>2</sub>

Hemoglobin A (400  $\mu$ M) was prepared in a 1 ml solution, in 100 mM phosphate (pH 7.4). Nitric oxide was added by injection of an appropriate volume of a 2 mM solution, stored under nitrogen. The solutions were vortexed vigorously in an open container. Samples were then analyzed by Saville assay and by chemiluminescence after UV photolysis. The results in Figure 17 show that S-nitrosothiol Hb can be formed from oxyHb, but that the efficiency of this formation is critically dependent upon the ratio of heme to nitric oxide.

Example 20: Formation of Oxidized Hb Dependent on Protein Concentration

Hemoglobin A was diluted to the concentrations indicated by the different symbols in Figure 18A and Figure 18B, in 50 ml of 100 mM phosphate buffer (pH 7.4). Nitric oxide was added by sequential injections of an appropriate volume of a 2 mM solution, stored under nitrogen. After each injection, the absorbance at 415 and 405 nm was measured. The ratio of these two absorbances was used to calculate the percentage content of oxidized hemoglobin (Figure 18A), and the absolute yield of oxidized hemoglobin (Figure 18B). ♦ represents 1.26  $\mu$ M hemoglobin, ■ represents 5.6  $\mu$ M hemoglobin, ▲ represents 7.0  $\mu$ M hemoglobin, X represents 10.3  $\mu$ M hemoglobin, ✕ represents 13.3  $\mu$ M hemoglobin, and ● represents 18.3  $\mu$ M hemoglobin. These data show that only a small proportion of the nitric oxide added results in the formation of oxidized hemoglobin (<10%). Furthermore, this tendency to form oxidized hemoglobin is reduced at higher protein concentrations.

Example 21: Effect of Ionic Strength and NO:Hb Ratio on  
Extent of MetHb Formation

We proposed that the degree of hydrogen bonding between bound oxygen and the distal histidine was critical in determining the degree of oxidation of hemoglobin by nitric oxide. Therefore, we examined the degree of oxidation of hemoglobin by nitric oxide in a variety of buffers. 5 ml of phosphate buffer containing 300  $\mu$ M hemoglobin A (~95% oxyHb) was placed in a 15 ml vial. Nitric oxide was added from a stock solution, 2 mM, stored under nitrogen. Immediately after nitric oxide addition, the absorbance at 630 nm was measured, and the concentration of oxidized (metHb) was plotted, using 4.4 as the extinction coefficient for metHb at 630 nm. Experiments were performed in 1 M, 100 mM, and 10 mM sodium phosphate buffer (pH 7.4). The data in Figure 19 show higher oxidized hemoglobin formation in 1M phosphate, which is indicative of a higher effective substrate concentration, as would be predicted by phosphate destabilization of the hydrogen bond between iron bound oxygen and the distal histidine. At the lowest concentrations of nitric oxide added, S-nitrosothiol was formed under all conditions (approximately 5  $\mu$ M). Additions of nitric oxide at concentrations of 30  $\mu$ M or greater resulted in the additional formation of nitrite. The presence of 200 mM borate within the buffer reduced oxidized hemoglobin and nitrite formation, whilst the presence of either 200 mM or chloride increased the formation of oxidized hemoglobin and nitrite. Addition of nitric oxide to hemoglobin in 10 mM phosphate buffer at a ratio of less than 1:30 (NO:Hemoglobin A) resulted in the formation of S-nitrosothiol without production of oxidized hemoglobin. S-nitrosothiol formation was optimized by adding the nitric oxide to hemoglobin in 10 mM phosphate, 200 mM borate, pH 7.4. Therefore, the balance between

oxidation and nitrosothiol formation is dependent upon the ratio of nitric oxide to hemoglobin and the buffer environment.

Example 22: Oxygen-Dependent Vasoactivity of S-

5 Nitrosohemoglobin: Contraction of Blood Vessels in R-  
Structure and Dilation in T-Structure

The details of this bioassay system have been published (Osborne, J.A., et al., *J. Clin. Invest.* 83:465-473 (1989)). In brief, New Zealand White female rabbits  
10 weighing 3-4 kg were anesthetized with sodium pentobarbital (30 mg/kg). Descending thoracic aorta were isolated, the vessels were cleaned of adherent tissue, and the endothelium was removed by gentle rubbing with a cotton-tipped applicator inserted into the lumen. The vessels  
15 were cut into 5-mm rings and mounted on stirrups connected to transducers (model TO3C, Grass Instruments, Quincy, MA) by which changes in isometric tension were recorded. Vessel rings were suspended in 7 ml of oxygenated Kreb's buffer (pH 7.5) at 37°C and sustained contractions were  
20 induced with 1  $\mu$ M norepinephrine.

Best attempts were made to achieve equivalent baseline tone across the range of oxygen concentrations; i.e., hypoxic vessels were contracted with excess phenylephrine. Oxygen tension was measured continuously using O<sub>2</sub>  
25 microelectrodes (Model 733 Mini; Diamond General Co., MI) (Young, W., *Stroke*, 11:552-564 (1980); Heiss, W.D. and Traupett, H., *Stroke*, 12:161-167 (1981); Dewhirst, M.W. et al., *Cancer Res.*, 54:3333-3336 (1994); Kerger, H. et al., *Am. J. Physiol.*, 268:H802-H810 (1995)). Less than 1% O<sub>2</sub>  
30 corresponds to 6-7 torr. Hypoxic vessels were contracted with excess phenylephrine to maintain tone. SNO-Hb[FeII]O<sub>2</sub> (SNO-oxyHb) preparations were synthesized and quantified as in Example 27; GSNO was prepared and assayed as described in Stamler, J.S. and Feelisch, M., "Preparation and

Detection of S-Nitrosothiols," pp. 521-539 in *Methods In Nitric Oxide Research* (M. Feelisch and J.S. Stamler, eds.), John Wiley & Sons Ltd., 1996.

Hemoglobin is mainly in the R (oxy)-structure in both  
5 95% O<sub>2</sub> or 21% O<sub>2</sub> (room air) (M.F. Perutz, pp. 127-178 in  
*Molecular Basis of Blood Diseases*, G. Stamatayanopoulos,  
Ed. (W.B. Saunders Co., Philadelphia, 1987); Voet, D. and  
Voet, J.G. (John Wiley & Sons Inc., New York, 1995) pp.  
215-235). Hb and SNO-Hb both contract blood vessels over  
10 this range of O<sub>2</sub> concentrations. That is, their hemes  
sequester NO from the endothelium. The functional effects  
of these hemoproteins in bioassays are not readily  
distinguished (Figure 20A). Concentration-effect responses  
of SNO-Hb are virtually identical to those of native Hb in  
15 95% O<sub>2</sub>--i.e., in R-structure (curves are not different by  
ANOVA; n=12 for each data point). Comparable contractile  
effects were seen with up to 50  $\mu$ M SNO-oxyHb/oxyHb--i.e.,  
at doses where the responses had plateaued. Similar  
concentration-effect responses were observed in 21% O<sub>2</sub>,  
20 under which condition Hb/SNO-Hb is ~99% saturated.

On the other hand, hypoxia (<1% O<sub>2</sub> [ $\sim$ 6 mm Hg]  
simulating tissue PO<sub>2</sub>) which promotes the T-structure (M.F.  
Perutz, pp. 127-178 in *Molecular Basis of Blood Diseases*,  
G. Stamatayanopoulos, Ed. (W.B. Saunders Co.,  
25 Philadelphia, 1987); Voet, D. and Voet, J.G. (John Wiley &  
Sons Inc., New York, 1995) pp. 215-235), differentiates Hb  
and SNO-Hb activities: Hb strongly contracts blood vessels  
in T structure whereas SNO-Hb does not (Figure 20B).  
Concentration-effect responses of SNO-Hb and Hb are  
30 significantly different <1% O<sub>2</sub> ( $\sim$ 6 torr), i.e. in T-  
structure. Native deoxyHb is a powerful contractile agent  
whereas SNO-deoxyHb has a modest effect on baseline tone.  
(In most experiments SNO-Hb caused a small degree of  
contraction at lower doses and initiated relaxations at the  
35 highest dose; in some experiments (see Figure 21C) it

caused dose-dependent relaxations.) n=13 for each data point; \*P<0.05; \*\*\*P<0.001 by ANOVA.

SNO-Hb relaxations are enhanced by glutathione through formation of S-nitrosoglutathione (GSNO) (Figure 20C). The  
5 potentiation of SNO-Hb vasorelaxation by glutathione is inversely related to the  $PO_2$  (Figure 20C) because NO group transfer from SNO-Hb is promoted in the T-structure. Specifically, transnitrosation of glutathione by SNO-Hb--forming the vasodilator GSNO--is accelerated in T-structure  
10 (<1%  $O_2$ ). Addition of 10  $\mu M$  glutathione to bioassay chambers potentiates the vasorelaxant response of SNO-Hb. The potentiation is greatest under hypoxic conditions; i.e., the curve for <1%  $O_2$  shows a statistically significant difference from both the 95% and 21%  $O_2$  curves  
15 (P<0.001), which are not different from one another by ANOVA (n=6 for all data points). High concentrations of glutathione (100  $\mu M$ -1 mM) further potentiate SNO-Hb relaxations, such that the response is virtually identical to that seen in the presence of GSNO in Figure 20D.  
20 Glutathione at 10  $\mu M$  has no effect on native Hb contractions.

In contrast, the vasorelaxant effects of S-nitrosoglutathione are largely independent of  $PO_2$  (Figure 20D) and unmodified by superoxide dismutase. (Data not  
25 shown.) Concentration-effect responses of S-nitrosoglutathione (GSNO) are largely independent of  $PO_2$  in the physiological range (n=6 at each data point). Results are consistent with known resistance of GSNO to  $O_2/O_2^-$  inactivation (Gaston, B. et al., *Proc. Natl. Acad. Sci.*  
30 *USA*, 90:10957-10961 (1993)). Thus, in T-structure, relaxation by SNO overwhelms the contraction caused by NO scavenging at the heme, whereas the opposite is true in R-structure.

Example 23: Bioactivity of Intraerythrocytic S-Nitrosohemoglobin (SNO-RBCs)

Contractile effects of RBCs are reversed by intracellular SNO-Hb in low but not high  $PO_2$ --i.e., under  
5 conditions that promote the T-structure. Low and high dose effects of SNO-RBCs are shown in Figures 21A and 21B, respectively.

Preparation of vessel rings and methods of bioassay are described in Example 22. SNO-oxyHb was synthesized and  
10 quantified as described in Example 27. Red blood cells containing SNO-Hb (SNO-RBCs) were synthesized by treatment with tenfold excess S-nitrosocysteine over hemoglobin for 5-10 min. Under this condition, red blood cells are bright red and contain SNO-oxyHb; methHb was not detectable in  
15 these experiments.

Red blood cells containing SNO-Hb (SNO-RBCs) function in vessel ring bioassays like cell-free SNO-Hb. In particular, low concentrations of SNO-RBCs ( $\sim 0.1 \mu M$  SNO-Hb) elicited modest contractile effects in 95%  $O_2$ , but not  
20 under hypoxia (Figure 21A). In 95%  $O_2$ , both SNO-RBCs ( $\sim 0.1 \mu M$  SNO-Hb[FeII] $O_2$ ) and native RBCs produced modest contractile effects that were not readily distinguished. The contractions by RBCs tended to be greater under hypoxic conditions ( $< 1\% O_2$ ), whereas those of SNO-RBCs were  
25 reversed (slight relaxant effects were seen). These  $O_2$ -dependent responses of SNO-RBCs closely resemble those of cell-free preparations. Hemolysis was minor and could not account for the observed effects.

At higher concentrations, SNO-RBCs produced small  
30 transient relaxations in 95%  $O_2$  and larger sustained relaxations under hypoxia (Figure 21B), much like cell-free SNO-Hb in the presence of glutathione. For example, SNO-RBCs ( $\sim 1 \mu M$  SNO-Hb[FeII] $O_2$ ) caused  $32.5 \pm 1.2\%$  relaxation that lasted  $14.5 \pm 0.7$  min. in 95%  $O_2$  versus  $61 \pm 10\%$   
35 relaxation that lasted  $23 \pm$  min. in  $< 1\% O_2$  ( $n=3-4$ ;  $P < 0.05$ ).

In contrast, RBCs containing no SNO-Hb produced small contractions (less than those of cell-free Hb) that are potentiated by hypoxia ( $13 \pm 2.0\%$  in 95% O<sub>2</sub> vs.  $25 \pm 5\%$  in <1% O<sub>2</sub>;  $P < 0.05$ ). Hemolysis in these experiments was minor and  
5 could not account for the extent of relaxation by SNO-RBCs.

In 95% O<sub>2</sub>, SNO-RBCs ( $\sim 1 \mu\text{M}$  SNO-Hb[FeII]O<sub>2</sub>) produced relaxations of aortic rings, whereas native RBCs produced slight contractions. Both effects were more prominent at low PO<sub>2</sub>. That is, relaxations and contractions of  
10 intraerythrocytic SNO-Hb and Hb, respectively, were greater and longer-lived in <1% O<sub>2</sub> than in 95% O<sub>2</sub>. The O<sub>2</sub>-dependent responses of SNO-RBCs mimicked those of cell-free SNO-Hb in the presence of glutathione. Hemolysis in these  
15 experiments was minor and could not account for the extent of relaxation by SNO-RBCs.

The normal response of systemic arteries to hypoxia is dilation and contraction to high PO<sub>2</sub>. The responses of vessel rings to changes in PO<sub>2</sub> in the presence of SNO-Hb and Hb were tested (Figure 21C). Vessel rings were  
20 contracted with phenylephrine under hypoxic conditions (6-7 torr) and then exposed to either 1  $\mu\text{M}$  Hb or SNO-Hb. Hb produced progressive increases in vessel tone, while SNO-Hb caused relaxations. Introduction of 95% O<sub>2</sub> led to rapid contractions in both cases. Thus, structural changes in  
25 SNO-Hb effected by PO<sub>2</sub> are rapidly translated into contractions or relaxations, whereas Hb contracts vessels in both R- and T-structures. Thus, Hb opposes the physiological response and SNO-Hb promotes it (Figure 21C). Direct effects of O<sub>2</sub> on smooth muscle operate in concert  
30 with SNO-Hb to regulate vessel tone.

Example 24: Influence of O<sub>2</sub> Tension on Endogenous Levels  
of S-Nitrosohemoglobin (SNO/Hb) and Nitrosyl Hemoglobin  
(FeNO/Hb)

Allosteric control of SNO-Hb by O<sub>2</sub> was assessed in  
5 vivo by perturbation of the periarteriolar oxygen gradient.  
In animals breathing room air (21% O<sub>2</sub>), the precapillary  
resistance vessels (100-10 µm) are exposed to PO<sub>2</sub>s as low  
as 10-20 torr (Duling, B. and Berne, R.M. *Circulation  
Research*, 27:669 (1970); Popel, A.S., et al., (erratum *Am.  
10 J. Physiol.* 26(3) pt. 2) *Am. J. Physiol.* 256, H921 (1989);  
Swain, D.P. and Pittman, R.N., *Am. J. Physiol.* 256, H247-  
H255 (1989); Buerk, D. et al., *Microvasc. Res.*, 45:134-148  
(1993)) (confirmed here) which promotes the T-structure in  
Hb. Raising the inspired oxygen concentration to 100%  
15 translates to periarteriolar PO<sub>2</sub>s only as high as 40 mm Hg  
(Duling, B. and Berne, R.M. *Circulation Research*, 27:669  
(1970); Popel, A.S., et al., (erratum *Am. J. Physiol.* 26(3)  
pt. 2). *Am. J. Physiol.* 256, H921 (1989); Swain, D.P. and  
Pittman, R.N. *Am. J. Physiol.* 256, H247-H255 (1989); Buerk,  
20 D. et al., *Microvasc. Res.*, 45:134-148 (1993)); i.e.,  
breathing 100% O<sub>2</sub> may not fully maintain the R-structure in  
Hb in the microcirculation. Elimination of the  
periarteriolar O<sub>2</sub> gradient (artery-arteriole and arterial-  
venous difference in PO<sub>2</sub>) is accomplished in hyperbaric  
25 chambers by applying 3 atmospheres of absolute pressure  
(ATA) while breathing 100% O<sub>2</sub> (Tibbles, P.M. and Edelsberg,  
J.S., *N.E.J.M.*, 334:1642-1648 (1996)).

Adult male Sprague-Dawley rats (290-350g) were  
anesthetized with sodium pentobarbital (50 mg/kg IP),  
30 intubated and ventilated with a small animal respirator  
(Edco Scientific Inc., Chapel Hill, NC) at a rate and tidal  
volume to maintain normal values of PaCO<sub>2</sub> (35-45 mm Hg;  
PaCO<sub>2</sub> = systemic arterial blood carbon dioxide tension).  
The femoral vein and artery were cannulated for infusion of  
35 drugs and for continuous monitoring of systemic blood

pressure, respectively. Aliquots of arterial blood (200  $\mu$ l) were drawn periodically to measure blood gas tensions and pH (Instrumentation Laboratory Co., model 1304 blood gas/pH analyzer). The blood was replaced intravenously  
5 with three volumes of normal saline. The inspired O<sub>2</sub> concentration was varied using premixed gases balanced with nitrogen. The tissue PO<sub>2</sub> was measured continuously with polarographic platinum microelectrodes (50  $\mu$ m O.D. coated with hydrophobic gas permeable Nafion) implanted  
10 stereotaxically in both the right and left hippocampus (AP-3.4 mm, ML+2.2 mm), caudate putamen nucleus and substantia nigra (see coordinates below) (Young, W., *Stroke*, 11:552-564 (1980); Heiss, W.D. and Traupett, H., *Stroke*, 12:161-167 (1981); Dewhirst, M.W. et al., *Cancer Res.*, 54:3333-  
15 3336 (1994); Kerger, H. et al., *Am. J. Physiol.*, 268:H802-H810 (1995)). The PO<sub>2</sub> electrodes were polarized to -0.65V against a distant Ag/AgCl reference located on the tail and the current flow was measured using a low-impedance nA-meter. Regional arterial PO<sub>2</sub> was adjusted by changing the  
20 inspired O<sub>2</sub> concentration and atmospheric pressure.

Polarographic hydrogen (H<sub>2</sub>)-sensitive microelectrodes were implanted stereotaxically in the substantia nigra (AP -5.3 mm, ML -2.4 mm to the bregma, depth 3.2 mm), caudate putamen nucleus (CPN) (AP +0.8 mm, ML -2.5 mm,  
25 depth 5.2 mm) and parietal cortex, for measurement of regional blood flow (Young, W., *Stroke*, 11:552-564 (1980); Heiss, W.D. and Traupett, H., *Stroke*, 12:161-167 (1981)). The microelectrodes were made from platinum wire and insulated with epoxy, with the exception of the tip (1 mm)  
30 which was coated with Nafion. For placement, the electrodes were mounted on a micromanipulator and the rat's head was immobilized in a Kopf stereotaxic frame. H<sub>2</sub>-sensitive electrodes were polarized to +400 mV against a distant reference electrode on the tail, and the  
35 polarographic current was measured using a low-impedance nA

meter during and after the inhalation of hydrogen gas (2.5%) for 1 min. Both the hydrogen clearance curves and voltage for oxygen measurements were made using PC WINDAQ (software, DI-200 AC, Dataq Instruments, Inc., Akron, OH).

5 Cerebral blood flow was calculated using the initial slope method (Young, W., *Stroke*, 11:552-564 (1980); Heiss, W.D. and Traupett, H., *Stroke*, 12:161-167 (1981)). Regional blood flow responses were monitored for 30 min. prior to and 30 min. following drug administration; hemoglobins were  
10 given at time 0.

Blood was drawn from indwelling catheters in the carotid artery (arterial blood that perfuses the brain) and superior vena cava/right atrium (venous return to the heart) of 5 rats exposed first to room air (21% O<sub>2</sub>) and  
15 then 100% O<sub>2</sub> + 3 ATA in a hyperbaric chamber. Levels of SNO-Hb and nitrosyl Hb (Hb[Fe]NO) were determined from these samples as a measure of SNO-Hb and nitrosyl Hb (Hb[Fe]NO; FeNO/Hb in Figure 9) in blood that perfuses the brain. The mean O<sub>2</sub> saturation of venous blood (room air)  
20 was 69%; of arterial blood (room air) was 93%; of venous blood (100% + 3 ATA) was also 93% and of arterial blood (100% + 3 ATA) was 100% (Figure 22). Numerous statistical comparisons were highly significant. For example, SNO-Hb venous 100% O<sub>2</sub> + 3 ATA vs. SNO-Hb venous 21% O<sub>2</sub>, P=0.004;  
25 and nitrosyl Hb venous 21% O<sub>2</sub> vs. arterial 21% O<sub>2</sub> P=0.008. On the other hand, SNO-Hb and nitrosyl Hb were not different in artery 21% O<sub>2</sub> compared with venous 100% + 3 ATA (which have identical O<sub>2</sub> saturations), nor did the differences reach significance between venous and arterial  
30 100% O<sub>2</sub> + 3 ATA. n=5 for all measurements.

In 21% O<sub>2</sub>, venous blood contained mostly nitrosyl Hb, whereas arterial blood contained significant amounts of SNO-Hb (Figure 22). On the other hand, SNO-Hb predominated in both arterial and venous blood in 100% O<sub>2</sub> + 3 ATA  
35 (Figure 22). In hyperbaric conditions, the tissues are

oxygenated primarily by  $O_2$  dissolved in plasma.

Physiologically circumventing the unloading of  $O_2$  by Hb alters the endogenous SNO/nitrosyl Hb balance. The data show that SNO-Hb appears to form endogenously in R-

- 5 structure whereas SNO is released in the T-structure (compare venous 21%  $O_2$  (T-state) with arterial 100%  $O_2$  + 3 ATA (R-state)).

This structure-function relationship *in vivo* is consistent with both the *in vitro* pharmacology and the  
10 molecular model suggesting that 1)  $O_2$  is an allosteric effector of Hb S-nitrosylation; 2) binding of NO to hemes of Hb is favored in the T-structure; (some of the NO released during arterial-venous (A-V) transit appears to be autocaptured at the hemes) and 3) maintaining endogenous  
15 SNO-Hb in the R-structure by eliminating the A-V  $O_2$  gradient preserves levels of SNO (compare venous 100%  $O_2$  + 3 ATA with arterial 21%  $O_2$ ). Thus, it can be predicted that SNO-Hb should improve cerebral blood flow in 21%  $O_2$ , under which condition SNO is readily released during A-V  
20 transit, but not under the hyperoxic conditions that maintain the R-structure in artery and vein.

#### Example 25: $O_2$ -Dependent Effects of SNO-Hb and Hb on Local Cerebral Blood Flow

The cerebrovascular effects of SNO-Hb were measured in  
25 adult male Sprague-Dawley rats using  $O_2$  and  $H_2$  (blood flow)-sensitive microelectrodes that were placed stereotaxically in several regions of the brain as for Example 24.

SNO-Hb increases blood flow under tissue hypoxia,  
30 whereas it decreases blood flow under hyperoxia. In contrast, Hb decreases blood flow irrespective of the  $PO_2$ . Comparative effects of SNO-Hb (●) and Hb (■) (1  $\mu\text{mol/kg}$  infused over 3 minutes) on local blood flow in substantia nigra (SN), caudate putamen nucleus, and parietal cortex

are shown for three different conditions. In 21% O<sub>2</sub>, SNO-Hb improved blood flow in all three regions of the brain tested, whereas native Hb decreased local blood flow, paradoxically attenuating O<sub>2</sub> delivery to hypoxic tissues (Figures 23A, 23B and 23C; all curves are highly statistically significantly different from one another and from baseline by ANOVA). In rats breathing 100% O<sub>2</sub>, where the periarteriolar O<sub>2</sub> gradient has been essentially eliminated, the increase in flow to SNO-Hb was significantly attenuated (i.e., only the SN increase reached statistical significance), but the Hb-mediated decrease in flow was preserved (Figures 23D, 23E and 23F; all curves remain different from one another by ANOVA to P<0.05). In 100% O<sub>2</sub> + 3 ATA, both SNO-Hb and Hb tended to decrease cerebral flow to similar extents (Figures 23G, 23H and 23I; curves are not different by ANOVA). S-nitrosoglutathione (GSNO) increased brain perfusion in 100% O<sub>2</sub> and 100% O<sub>2</sub> + 3 ATA, reversing protective vasoconstriction. Baseline blood flow was decreased by ~10% under 100% O<sub>2</sub> + 3 ATA as compared to 100% O<sub>2</sub>. n=7 for all data points. Values of tissue/microvascular PO<sub>2</sub> ranged from 19-37 mm Hg in 21% O<sub>2</sub>; from 68-138 mm Hg in 100% O<sub>2</sub>; and from 365-538 mm Hg in 100% + 3 ATA (Duke University Medical Center Hyperbaric Chambers).

SNO-Hb acts like native Hb (net NO scavenger) when it is in the R (oxy)-structure and like GSNO (net NO donor) in the T (deoxy)-structure. The results are consistent with the conclusion that SNO-Hb is a nitrosothiol whose vasoactivity is allosterically controlled by PO<sub>2</sub>.

Example 26: Hemodynamics of Cell Free and Intraerythrocytic SNO-Hb, Hb and GSNO at Different O<sub>2</sub> Concentrations

Rats were anesthetized by intraperitoneal injection of pentobarbital, and the femoral arteries and veins accessed

by local cutdown. The artery was then cannulated and the blood pressure monitored continuously using a P23 XL pressure transducer (Viggo Spectramed, Oxnard, CA) attached to a Gould recorder. The femoral vein was used for  
5 infusion of drugs and red blood cells containing SNO-Hb (1 ml over 1 min.) and an IBM PC (WINDAQ 200, Dataq Instruments, Inc.; Akron, OH) was used for data acquisition.

Drugs were infused through the femoral vein at 1  
10  $\mu\text{mol/kg}$  infused over 1 minute after blood pressure had stabilized (approximately 30 min). Measurements shown (Figure 24A) were taken at 10 min. post-infusion of drug. Similar responses were seen at 3 and 20 min. SNO-Hb produced significantly less of an increase in blood  
15 pressure than Hb ( $P < 0.05$ ), whereas GSNO decreased blood pressure.  $P < 0.05$  vs. SNO-Hb;  $*P < 0.05$ ,  $**P < 0.01$ ) vs. baseline blood pressure.  $n = 5-6$  for each drug.

Infusions of SNO-RBCs also lowered blood pressure consistent with a GSNO-like effect (Figure 24B). SNO-RBCs  
20 produced dose-dependent hypotensive effects (similar to those of cell-free SNO-Hb) ( $P < 0.001$  at all points vs. baseline). The hypotensive effects of SNO-RBCs were potentiated by pre-administration of the NO synthase inhibitor  $\text{N}^G$ -monomethyl-L-arginine (L-NMMA; 50 mg/kg).  $n = 8$   
25 for each data point. Curves different by ANOVA ( $P < 0.01$ ),  $*P < 0.05$  vs. L-NMMA. The amount of hemolysis in these experiments was trivial. Infusion of the hemolysate had no effect on blood pressure.

NO synthase inhibition increases tissue  $\text{O}_2$  consumption  
30 by relieving the inhibition of mitochondrial respiration produced by NO in the tissues (King, C.E. *et al.*, *J. Appl. Physiol.*, 76(3):1166-1171 (1994); Shen, W. *et al.*, *Circulation*, 92:3505-3512 (1995); Kobzik, L. *et al.*, *Biochem. Biophys. Res. Comm.*, 211(2):375-381 (1995)). This  
35 should, in turn, increase the periarteriolar  $\text{O}_2$  gradient

which might explain some of the potentiation. However, other factors, such as a change in tone or distribution of blood flow imposed by L-NMMA, may well contribute. The effects of SNO-Hb on blood pressure are consistent with SNO  
5 being released in resistance arterioles to compensate for NO scavenging at the heme iron.

Example 27: Synthesis of S-Nitroso-Oxyhemoglobin (SNO-Hb[Fe(II)]O<sub>2</sub>) and SNO-metHb (SNO-Hb[Fe(III)])

Hemoglobin (Hb)A<sub>0</sub> was purified from human red blood  
10 cells as previously described (Kilbourn, R.G. et al., *Biochem. Biophys. Res. Commun.*, 199:155-162 (1994)). HbA<sub>0</sub> was dialyzed against 2% borate, 0.5 mM EDTA (pH 9.2) at 4°C for 12-16 hours. The oxyHb concentration was determined based on the optical absorbance at 577 nm (i.e., using the  
15 millimolar extinction coefficient 14.6).

Hb was reacted with 10-fold molar excess S-nitrosocysteine (CYSNO) which was synthesized with modification of standard procedure (see, for example, Stamler, J.S. and Feelisch, M., "Preparation and Detection  
20 of S-Nitrosothiols," pp. 521-539 in *Methods In Nitric Oxide Research* (M. Feelisch and J.S. Stamler, eds.), John Wiley & Sons Ltd., 1996) as follows. L-cysteine hydrochloride (1.1 M) dissolved in 0.5 N HCl/0.5 mM EDTA was reacted with an equal volume of 1 M NaNO<sub>2</sub> (sodium nitrite) dissolved in  
25 water, to form CYSNO (the ratio of cysteine to nitrite influences the SNO-Hb product and activity profile). The concentration of CYSNO was then adjusted by dilution in 200 mM phosphate buffer (PBS), pH 8.0, to yield a working CYSNO solution (pH 6-7). This was then reacted at room  
30 temperature with a 20-fold volume excess of Hb (in borate, pH 9.2), resulting in a final 10-fold molar excess of CYSNO over Hb (ratio influences product critically). Following the incubation (periods determined by the desired synthetic preparation; i.e., a desired ratio of SNO/tetramer; desired

met- to oxy- to nitrosyl-Hb ratios; polynitrosated or non-  
polynitrosated; for example, 10 min. preferred time for  
SNO-oxyHb with 2 SNO per tetramer; see below), the reaction  
mixture was rapidly added to a column of fine Sephadex G-25  
5 (20 to 30-fold volume excess over the reaction mixture)  
preequilibrated with 100 mM PBS pH 7.4, 0.5 mM EDTA.  
Typically, a 150  $\mu$ l sample of the mixture was added to a  
4.5 ml column measuring 12 mm (inner diameter). The column  
was then centrifuged at 1200 g for 60 seconds and the  
10 effluent collected in a 1.5 ml airtight plastic vial that  
was subsequently kept on ice and protected from light.

Spectrophotometric determination of total Hb and S-  
nitrosothiol (SNO) concentration was determined by Saville  
assay (especially modified from standard protocol (see  
15 Materials and Methods section of Exemplification; see also,  
for example, Stamler, J.S. and Feelisch, M., "Preparation  
and Detection of S-Nitrosothiols," pp. 521-539 in *Methods  
In Nitric Oxide Research* (M. Feelisch and J.S. Stamler,  
eds.) John Wiley & Sons Ltd., 1996; Saville, B., *Analyst*,  
20 83:670-672 (1958)) by keeping the Hb in the sample to 5  $\mu$ l  
per 50  $\mu$ l sample volume added to assay, adding 0.1-1% Tween  
as necessary, and by correcting for nitrosyl Hb content  
converted to nitrite).

Incubations of CYSNO with HbA resulted in different  
25 synthetic products (and different activities) over time.  
For example, with 10 min incubations, the Hb preparation  
contains  $1.857 \pm 0.058$  SNO groups per tetramer, and is  
approximately 12-15% metHb and 1-3% nitrosyl(FeII)-  
hemoglobin. (Capillary electrophoretic analysis actually  
30 reveals a mixture of three protein peaks.) MetHb was then  
reduced (lowered from 13% to 2% with 100-fold excess  
NaCNBH<sub>3</sub> (dissolved in PBS, pH 8.0) under anaerobic  
conditions (achieved by purging with argon gas for a  
minimum of 10 minutes) for 5 minutes. (Lower  
35 concentrations of NaCNBH<sub>3</sub> or treatment of the samples under

aerobic conditions were not effective in lowering the methHb concentration, and alternative measures to reduce the heme result in SNO reduction.) The resulting mixture was rapidly added to a column of fine Sephadex G-25 (20 to 30-fold volume excess) preequilibrated with 100 mM PBS pH 7.4, 0.5 mM EDTA. The final S-nitrosothiol/Hb tetramer ratios were not significantly different from those measured in samples degassed and treated with PBS only: losses in SNO/Hb ratio relative to the starting ratios were consistent with the expected time-dependent decay of SNO-deoxyHb and could be reduced to an insignificant loss by taking preparative time into consideration. NaCNBH<sub>3</sub> treatment of a sample with a mean SNO/Hb ratio of ~1 decreased the methHb content from 5.6% to 0.63%.

Nitrosyl(FeII)-hemoglobin and methHb contamination of SNO-oxyHb preparations of ~2% are acceptable, inasmuch as they do not seem to alter bioactivity of SNO-oxyHb, and enable O<sub>2</sub> binding measurements, that is, P<sub>50</sub> determinations (so called SNO-Hb[Fe(II)]O<sub>2</sub>). By the same token, bioactivity can be modified and varied by controlling the proportion of SNO-methHb (high and low spin) and nitrosyl(FeII)-hemoglobin in the preparation. The spin state of methHb can be controlled by the heme ligand: cyan-methHb is low spin and aquo-met Hb (H<sub>2</sub>O bound as ligand) is high spin; nitrosyl Hb ratios are made depending on the desired result (see, inter alia, Example 16). High yield SNO-methHb, SNO-nitrosyl(FeII)-hemoglobin (or SNO-carboxyl Hb) can be formed by using the heme-liganded protein as starting material. Carboxyl Hb can be made by gassing with CO under anaerobic conditions. HbCO can then be used as starting material; likewise, various combinations of Hb[FeNO][FeCO] can be used as starting material.

Equivalents

Those skilled in the art will know, or be able to ascertain using no more than routine experimentation, many equivalents to the specific embodiments of the invention  
5 described herein. These and all other equivalents are intended to be encompassed by the following claims.

CLAIMS

What is claimed is:

1. A method for treating a disease or medical disorder in a mammal, comprising administering to the mammal a  
5 nitrosating agent.
2. The method of Claim 1 in which the nitrosating agent is selected for rapid entry into a target cell.
3. The method of Claim 1, wherein the disease or medical  
10 disorder is selected from the group consisting of:  
shock, angina, stroke, reperfusion injury, acute lung  
injury, sickle cell anemia and infection of red blood  
cells.
4. A composition comprising SNO-Hb[FeII]O<sub>2</sub> which is S-  
15 nitrosylated without detectable oxidation of the heme  
Fe.
5. A composition comprising SNO-Hb[FeII] which is S-  
nitrosylated without detectable oxidation of the heme  
Fe.
6. A method for delivering NO in a mammal, comprising  
20 administering to the mammal a blood substitute  
comprising nitrosated hemoglobin.
7. The method of Claim 6, in which the blood substitute  
further comprises low molecular weight S-nitrosothiol.
- 25 8. A method for treating a disease or medical condition  
in a mammal, comprising administering to the mammal a  
composition comprising a form of nitrosated or

5       nitrated hemoglobin, wherein the disease or medical condition is selected from the group consisting of heart disease, brain disease, vascular disease, atherosclerosis, lung disease, inflammation, stroke, angina and respiratory distress.

9.     A method for treating a human with sickle cell anemia comprising administering to the human a composition comprising SNO-Hb(FeII)O<sub>2</sub>.
10.    The method of Claim 9 in which the composition further comprises a thiol.
11.    The method of Claim 9 in which the composition further comprises an S-nitrosothiol.
12.    A method for treating a patient having a disease or medical condition characterized by abnormalities of nitric oxide and oxygen metabolism, comprising  
15       administering to the patient an effective amount of a preparation comprising nitrosated hemoglobin.
13.    The method of Claim 12 in which the disease or medical condition is selected from the group consisting of:  
20       heart disease, lung disease, sickle-cell anemia, stroke, sepsis and organ transplantation.
14.    A blood substitute comprising nitrosated or nitrated hemoglobin.
15.    A method for treating a disorder resulting from  
25       platelet activation or adherence in an animal or human, comprising administering to the animal or human a composition comprising nitrosated or nitrated hemoglobin in a therapeutically effective amount.

16. The method of Claim 15 wherein the disorder is selected from the group consisting of: myocardial infarction, pulmonary thromboembolism, cerebral thromboembolism, thrombophlebitis, sepsis and unstable angina.
17. A method for preventing thrombus formation in an animal or human, comprising administering a composition comprising nitrosated hemoglobin in a therapeutically effective amount.
18. A method for forming polynitrosated hemoglobin, comprising combining hemoglobin with an excess of S-nitrosothiol over hemoglobin tetramer in an aqueous solution, and maintaining the resulting combination under conditions appropriate for nitrosation to occur at multiple sites on hemoglobin.
19. A method for forming polynitrosated or polynitrated hemoglobin in which heme Fe is in the FeII state, comprising combining hemoglobin with an NO donating compound, maintaining the resulting combination under conditions appropriate for nitrosation or nitration to occur, thereby forming polynitrosated or polynitrated hemoglobin, and reacting the polynitrosated or polynitrated hemoglobin with a reagent which selectively reduces FeIII to FeII.
20. The method of Claim 19 in which the reagent which selectively reduces FeIII to FeII is a cyanoborhydride.
21. The method of Claim 19 in which the reagent which selectively reduces FeIII to FeII is methemoglobin reductase.

22. A composition comprising polynitrosated hemoglobin.
23. Method for treating or preventing a disease or medical disorder which can be ameliorated by delivery of NO or its biological equivalent to tissues affected by the disease or medical disorder, in an animal or human, comprising administering to the animal or human nitrosyl-heme-containing donors of NO.
24. The method of Claim 23 wherein the nitrosyl-heme-containing donor of NO is nitrosylhemoglobin.
25. Method for making stable nitrosyl-deoxyhemoglobin comprising adding NO to deoxyhemoglobin in an aqueous solution such that the ratio of NO:heme is less than about 1:100 or greater than about 0.75.
26. Method for making SNO-oxyhemoglobin, comprising adding NO to an aqueous solution of oxyhemoglobin and buffer having a pK of at least about 9.4, at a concentration of approximately 10 mM to 200 mM, at pH 7.4.
27. Method for making SNO-oxyhemoglobin, comprising adding NO to an aqueous solution of oxyhemoglobin in approximately 10 mM phosphate buffer at pH 7.4.
28. A composition comprising nitrosyl-deoxyhemoglobin in a physiologically compatible buffer, wherein the ratio of NO:heme is less than about 1:100 or greater than about 0.75.
29. Method for making nitrosyl-oxyhemoglobin comprising adding NO to oxyhemoglobin in an aqueous solution such that the ratio of NO:hemoglobin is less than about 1:30.

30. Hemoglobin conjugated to an NO-donor.
31. Hemoglobin of Claim 30, wherein the NO-donor is selected from the group consisting of:  
diazeniumdiolates, nitroprusside, nitroglycerin and nitrosothiol.
32. A composition comprising hemoglobin and one or more NO-donors.
33. A method for treating or preventing a disease or medical disorder which can be ameliorated by delivery of NO or its biological equivalent to tissues affected by the disease or medical disorder, in an animal or human, comprising administering a heme-based blood substitute and inhaled NO to the animal or human.
34. A method for delivering CO to the tissues in an animal or human, comprising administering CO-derivatized hemoglobin to the animal or human.
35. A method of treating or preventing a disease or medical disorder which can be ameliorated by delivery of NO or its biological equivalent to tissues affected by the disease or medical disorder in an animal or human, comprising administering both CO-derivatized hemoglobin and a nitrosated hemoglobin to the animal or human.
36. Nitrosylhemoglobin conjugated to one or more electron acceptors.
37. Nitrosylhemoglobin of Claim 36, wherein the electron acceptor is selected from the group consisting of superoxide dismutase, stable nitroxide radicals,

oxidized forms of nicotinamide adenine dinucleotide, nicotinamide adenine dinucleotide phosphate, flavin adenine dinucleotide, flavin mononucleotide, ascorbate and dehydroascorbate.

5 38. A composition comprising nitrosylhemoglobin and one or more electron acceptors.

39. A composition comprising S-nitrosohemoglobin in a pharmaceutically acceptable vehicle, wherein the S-nitrosohemoglobin is selected from the group  
10 consisting of SNO-Hb[FeII]O<sub>2</sub>, SNO-Hb[FeII]CO, and SNO-Hb[FeIII].

40. A method for measuring nitrosyl(FeII)-hemoglobin in blood comprising the steps of:  
15 a) lysing the red blood cells of a blood sample;  
b) preparing a protein fraction of the lysed red blood cells;  
c) subjecting a protein fraction to photolysis; and  
d) determining the amount of nitric oxide in the protein fraction by measuring a chemiluminescence  
20 signal generated by a chemical reaction between nitric oxide and ozone.

41. A method for measuring nitrosyl(FeII)-hemoglobin in venous blood comprising the steps of:  
25 a) lysing the red blood cells in a sample of venous blood;  
b) isolating a desalted protein fraction of the lysed red blood cells;  
c) subjecting the desalted protein fraction to photolysis; and  
30 d) determining the amount of nitric oxide in the desalted protein fraction by measuring a

chemiluminescence signal generated by a chemical reaction between nitric oxide and ozone.

42. A method for assaying S-nitrosohemoglobin comprising:
- a) isolating washed red blood cells from blood;
  - 5 b) lysing the red blood cells, thereby obtaining a lysate;
  - c) desalting the lysate;
  - d) contacting an aliquot of the lysate of c) with mercury ions in excess over protein
  - 10 concentration, thereby obtaining a mercury-treated aliquot and an untreated aliquot;
  - e) exposing the mercury-treated aliquot and the untreated aliquot to oxygen;
  - f) measuring NO equivalents in the mercury-treated
  - 15 aliquot of e) and NO equivalents in the untreated aliquot of e) by photolysis-chemiluminescence; and
  - g) determining a quantity of S-nitrosohemoglobin from the NO equivalents measured in f).
- 20 43. A method for assaying S-nitrosohemoglobin comprising:
- a) isolating washed red blood cells from blood;
  - b) lysing the red blood cells, thereby obtaining a lysate;
  - c) desalting the lysate;
  - 25 d) contacting an aliquot of the lysate with mercury ions in excess over protein concentration, thereby obtaining a mercury-treated aliquot and an untreated aliquot;
  - e) exposing the mercury-treated aliquot and
  - 30 untreated aliquot to oxygen;
  - f) isolating a mercury-treated low molecular weight fraction and an untreated low molecular weight fraction from the respective aliquots of e);

- g) contacting the low molecular weight fractions of f) with excess low molecular weight thiol under acidic conditions, thereby producing S-nitrosothiol in each fraction;
  - 5 h) measuring NO equivalents from S-nitrosothiol in the fractions of g) by photolysis-chemiluminescence; and
  - i) determining a quantity of S-nitrosohemoglobin from the NO equivalents measured in h).
- 10 44. A method for measuring S-nitrosohemoglobin and nitrosyl(FeII)-hemoglobin in red blood cells, comprising:
- a) isolating washed red blood cells from blood;
  - 15 b) lysing the red blood cells, thereby obtaining a lysate;
  - c) desalting the lysate; and
  - d) measuring NO equivalents from the lysate of c) by photolysis-chemiluminescence.
- 20 45. A method for measuring nitrosyl(FeII)-hemoglobin in venous blood, comprising:
- a) isolating washed red blood cells from venous blood;
  - b) lysing the red blood cells, thereby obtaining a lysate;
  - 25 c) desalting the lysate; and
  - f) determining NO equivalents in the lysate by photolysis-chemiluminescence, thereby measuring nitrosyl(FeII)-hemoglobin.
- 30 46. A method for assaying nitrosyl(Fe)-hemoglobin comprising:
- a) isolating washed red blood cells from blood;

- b) lysing the red blood cells, thereby obtaining a lysate;
  - c) desalting the lysate;
  - d) contacting an aliquot of the lysate with mercury  
5 ions in excess over protein concentration,  
thereby obtaining a mercury-treated aliquot and  
an untreated aliquot;
  - e) exposing the mercury-treated aliquot and  
untreated aliquot to oxygen;
  - 10 f) measuring NO equivalents in the aliquots of e) by  
photolysis-chemiluminescence, thereby obtaining  
1) a quantity for S-nitrosohemoglobin and 2) a  
quantity for nitrosyl(FeII)-hemoglobin and S-  
nitrosohemoglobin combined, respectively; and
  - 15 g) determining a quantity for nitrosyl(FeII)-  
hemoglobin by subtracting 1) from 2).
47. A method for assessing oxygen delivery to a site in  
the body, comprising determining S-nitrosohemoglobin  
and nitrosylhemoglobin values in a blood sample from  
20 the site, and using said values to assess oxygen  
delivery.
48. The method of Claim 47, further comprising determining  
an oxygen value in the blood sample and using said  
value to assess oxygen delivery.

NO-MODIFIED HEMOGLOBINS AND USES THEREFOR

Abstract of the Disclosure

S-nitrosohemoglobin (SNO-Hb) can be formed by reaction of Hb with S-nitrosothiol and by other methods described  
5 herein which do not result in oxidation of the heme Fe. Other methods can be used which are not specific only for thiol groups, but which nitrosate Hb more extensively, and may produce polynitrosated metHb as a product or  
10 intermediate product of the method. SNO-Hb in its various forms and combinations thereof (oxy, deoxy, met; specifically S-nitrosylated, or nitrosated or nitrated to various extents) can be administered to an animal or human where it is desired to oxygenate, to scavenge free  
15 radicals, or to release NO<sup>+</sup> groups to tissues. Thiols and/or NO donating agents can also be administered to enhance the transfer of NO<sup>+</sup> groups. Examples of conditions to be treated by SNO-Hbs or other nitrosated or nitrated forms of Hb include ischemic injury, hypertension, angina, reperfusion injury and inflammation, and disorders  
20 characterized by thrombosis. Further embodiments of the invention are methods for assessing oxygen delivery to the tissues of a mammal by measuring SNO-Hb and nitrosylhemoglobin in blood.

FIG. 7B is a line graph showing the normalized maximal extent of aggregation for SNO-Hemoglobin Fe(II): Oxy-Hb at concentrations of 10nm, 100nm, 1um, 10um, and 100um. The y-axis ranges from 0 to 1.0. The x-axis is labeled 'Concentration' with values 10nm, 100nm, 1um, 10um, and 100um. The data points are approximately: 10nm (0.92), 100nm (0.90), 1um (0.88), 10um (0.85), and 100um (0.62). Error bars are present for the first four points.

## IN THE UNITED STATES PATENT AND TRADEMARK OFFICE

Declaration for Patent Application

As a named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated next to my name;

I believe I am the original, first and sole inventor (if only one name is listed) or an original, first and joint inventor (if plural names are listed in the signatory page(s) commencing at page 3 hereof) of the subject matter which is claimed and for which a patent is sought on the invention entitled

NO-MODIFIED HEMOGLOBINS AND USES THEREFOR

the specification of which (check one)

☒ is attached hereto.

☐ was filed on \_\_\_\_\_ as United States Application Number or PCT International Application Serial No. \_\_\_\_\_ and was amended on \_\_\_\_\_ (if applicable).

I hereby state that I have reviewed and understand the contents of the above-identified specification, including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose information which is known by me to be material to patentability as defined in 37 C.F.R. §1.56.

I hereby claim foreign priority benefits under Title 35, United States Code, §119 of any foreign application(s) for patent or inventor's certificate listed below and have also identified below any foreign application for patent or inventor's certificate having a filing date before that of the application on which priority is claimed:

<u>Prior Foreign Application(s)</u>			Priority Not Claim
_____ (Number)	_____ (Country)	_____ (Day/Month/Year filed)	[ ]
_____ (Number)	_____ (Country)	_____ (Day/Month/Year filed)	[ ]
_____ (Number)	_____ (Country)	_____ (Day/Month/Year filed)	[ ]

I hereby claim the benefit under 35 U.S.C. §119(e) of any United States provisional application(s) listed below.

<u>60/003,801</u> (Application Number)	<u>September 15, 1995</u> (Filing Date)
_____ (Application Number)	_____ (Filing Date)

I hereby claim the benefit under Title 35, United States Code, §120 of any United States application(s) listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States application in the manner provided by the first paragraph of Title 35, United States Code, §112, I acknowledge the duty to disclose information known by me to be material to patentability as defined in 37 C.F.R. §1.56 which occurred between the filing date of the prior application and the national or PCT international filing date of this application:

<u>08/796,164</u> (Application Serial No.)	<u>02/06/97</u> (Filing date)	<u>Pending</u> (Status, patented, pending, abandoned)
<u>PCT/US96/14659</u> (Application Serial No.)	<u>09/13/96</u> (Filing date)	<u>Pending</u> (Status, patented, pending, abandoned)
<u>PCT/US96/14660</u> (Application Serial No.)	<u>09/13/96</u> (Filing date)	<u>Pending</u> (Status, patented, pending, abandoned)
<u>08/667,003</u> (Application Serial No.)	<u>06/20/96</u> (Filing date)	<u>Pending</u> (Status, patented, pending, abandoned)
<u>08/616,371</u> (Application Serial No.)	<u>03/15/96</u> (Filing date)	<u>Pending</u> (Status, patented, pending, abandoned)
<u>08/616,259</u> (Application Serial No.)	<u>03/15/96</u> (Filing date)	<u>Pending</u> (Status, patented, pending, abandoned)

As a named inventor, I hereby appoint the following attorney(s) and/or agent(s) to prosecute this application and transact all business in the Patent and Trademark Office connected therewith.

I also hereby grant additional Powers of Attorney to the following attorney(s) and/or agent(s) to file and prosecute an international application under the Patent Cooperation Treaty based upon the above-identified application, including a power to meet all designated office requirements for designated states:

David E. Brook	Reg. No. 22,592	Thomas O. Hoover	Reg. No. 32,470
James M. Smith	Reg. No. 28,043	Alice O. Carroll	Reg. No. 33,542
